SECTION 1—INTRODUCTION

This instruction bulletin details information about installing, operating, and maintaining ventilated and nonventilated dry type transformers. Each transformer has its own specification and unique construction features. These features are detailed in the transformer outline and nameplate drawings.

This instruction bulletin is not an application guide for the ventilated dry type transformers or a substitute for adequate training in safe working procedures for this and related electrical equipment. Installation of this electrical equipment may require special licenses or training. Consult applicable national, industry, and local codes for specific requirements.

The successful operation of any transformer depends on various factors such as installation, loading, service conditions, and maintenance. Electrical systems in which transformers, along with vacuum or SF^6 circuit breakers, are used are capable of high frequency overvoltages which will not be suppressed by lightning arresters. These medium voltage systems may require a detailed, high frequency overvoltage system analysis and/or the addition of high frequency overvoltage protection. The transformer should be installed in conditions as specified in ANSI/IEEE Section C57.12.01 *Usual Service Conditions*, unless the transformer is designed specifically for operation in conditions other than the usual service conditions.

NOTE: If additional information is needed that is not covered by this instruction bulletin, contact the nearest Schneider Electric Field Sales Office, or Square D Services at 1-800-634-2003.

SECTION 2—
SAFETY PRECAUTIONS

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- Read and understand this entire instruction bulletin before installing, operating, or maintaining a dry type transformer. Follow all applicable local and national codes.
- Disconnect all power and verify the transformer is de-energized before servicing the transformer. Operation of a primary protective device may be evidence of a faulted transformer. Do not re-energize the transformer until the cause of operation of the primary protective device is found and corrected.
- Many parts of the transformer operate at high voltages. DO NOT TOUCH. Use only electrically insulated tools and clothing, and protective gear when working around electrical equipment.
- Do not rely on visual indications such as switch position or fuse removal for determining a de-energized condition. Always assume that a terminal is energized unless it is checked with a properly rated meter to ensure the terminal is de-energized and grounded.
- Before servicing the transformer, ensure all static charge has been discharged by grounding the coils with an appropriate grounding device.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors, and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

SECTION 3—RECEIVING, HANDLING, AND STORAGE

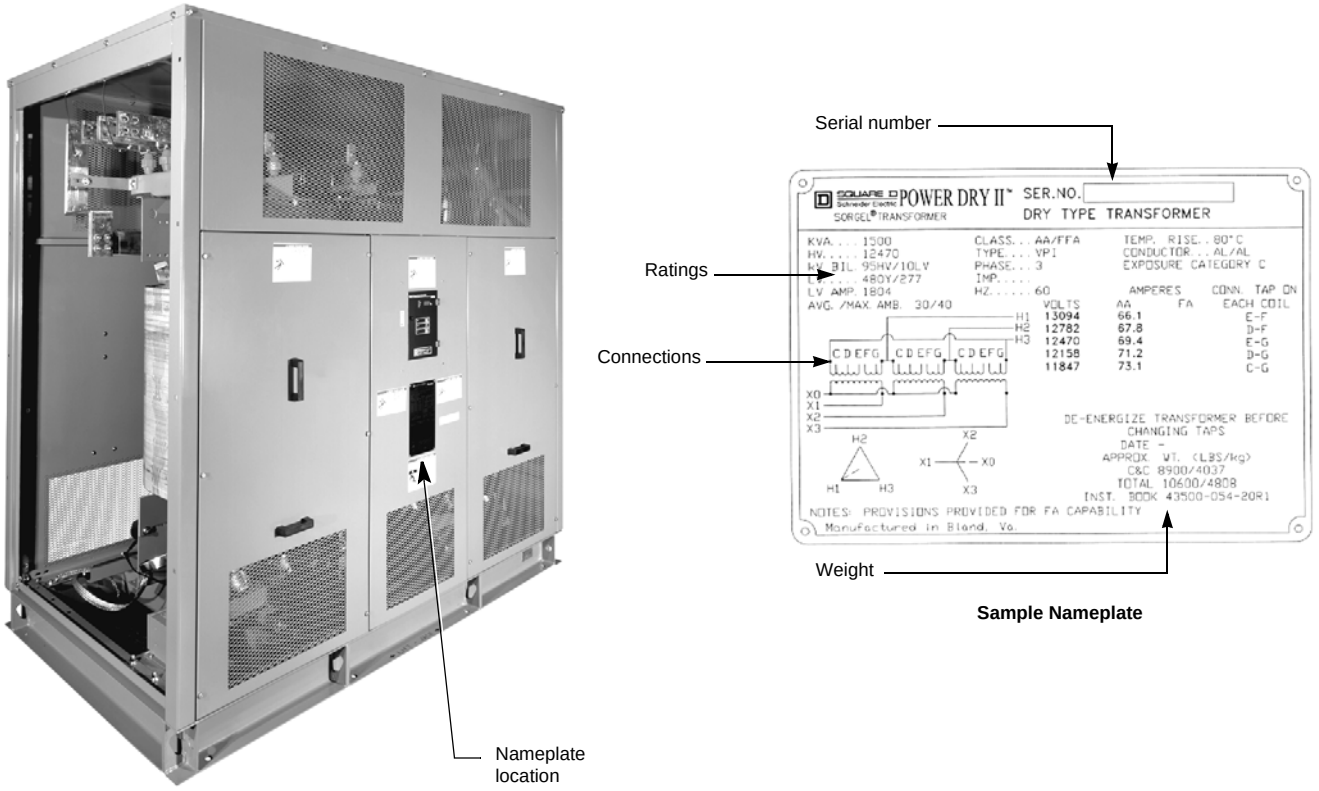
Ventilated open wound transformers are shipped either completely assembled in a sheet metal enclosure or as a core and coil assembly. They are covered with a clear plastic sheet to prevent entrance of moisture and dust.

Figure 1: Typical Packaging of Transformers for Shipment

Typical Packaging for an Enclosed-indoor Ventilated Dry Transformer

Typical Crating and Cover for a Core and Coil Assembly

Initial Inspection



Before unloading the transformer, perform the following inspection:

1. Remove the protective covering.
2. Verify that the serial number on the transformer nameplate (Figure 2 on page 8) matches the serial number listed on the bill of lading. If the numbers do not match, contact your field sales representative immediately.
3. Review the shipping papers to ensure shipment is complete. Accessories, hardware, or both may arrive in a separate container on a separate pallet.
4. Inspect the transformer for any obvious external damage that may have occurred during shipment. An internal inspection of the enclosure is not usually required unless possible external damage has been observed. If an internal inspection is required, carefully inspect the leads, bolted mechanical and electrical joints, the core and coils, and accessory equipment such as fans, controls, heater strips, control power transformers, or current transformers. List any noticeable damage on the receiving papers, file a claim with the carrier at once, and notify Schneider Electric .
5. After completing all of the above steps and if no problems are found, off load the transformer. Refer to “Handling” below.

Handling

Observe the following safety measures when handling the transformer:

⚠ DANGER

HAZARD OF FALLING EQUIPMENT AND CRUSHING

- Transformer is top heavy and may become unbalanced.
- Verify that the capacity of the handling equipment is adequate for the transformer weight.
- Keep all unnecessary personnel away while handling and moving the transformer.

Failure to follow these instructions will result in death or serious injury.

Unloading and Lifting

Whenever possible, use a crane to unload the transformer. In some cases, smaller transformers may be shipped in a box-type trailer that cannot be unloaded with a crane. In these cases, a forklift may be used to unload the transformer.

The approximate weight of the transformer is shown on the nameplate. Verify that the capacity of the handling equipment is adequate for the weight of the transformer.

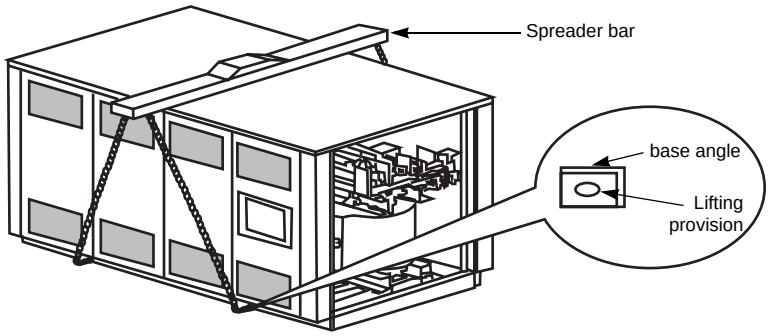
ENGLISH

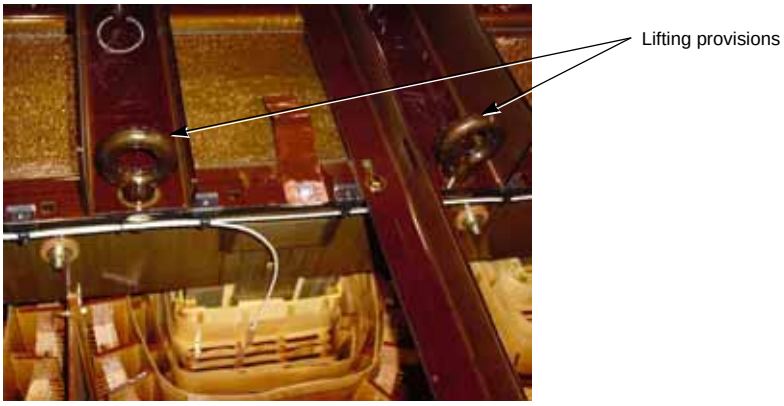


External Lifting Procedures

The transformer assembly may be lifted from provisions on the base frame using lifting slings, chains, or cables with spreaders. Care should be taken to avoid damage to the enclosure by allowing at least 20 feet from the top of the enclosure to the lift hook, or by using a spreader bar (Figure 3).

1. Use spreaders or spanner bars (Figure 3) to provide the vertical lift on lifting pads and slings to prevent crushing or otherwise damaging the frame or its finish.

Figure 3: Using a Spreader Bar



2. Select or adjust the rigging lengths to compensate for any unequal weight distribution of load and to maintain the transformer in an upright position.
3. Do not allow the angle between the lifting cables and vertical to exceed 45° in order to reduce the tension on the rigging and the compressive load on the lifting or spanner bars and spreaders.
4. Do not pass ropes or cables through the lift holes in bars, angles, or channels. Use slings with safety hooks or shackles.
5. Small cushioned pads may be placed on the transformer sides and cover to avoid contact with the enclosure.

Optional Lifting Procedures

If external lifting is not possible, removal of the enclosure top (Figure 4) allows easy attachment of shackles to the lifting provisions located on the top core clamps.

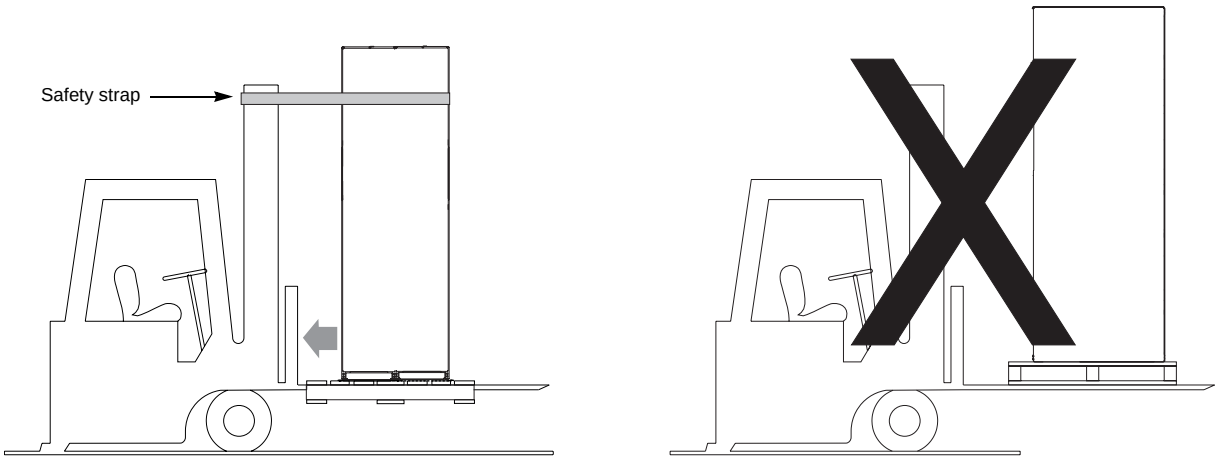
Figure 4: Recommended Method of Lifting from Overhead

NOTE: Cable pull angles should not exceed 45° from vertical. Avoid tilting. Unit is top heavy.

© 1999–2005 Schneider Electric All Rights Reserved

Using a Forklift

If the transformer must be unloaded with a forklift, observe the following safety precautions.



⚠ DANGER

HAZARD OF FALLING EQUIPMENT AND CRUSHING

- Transformer is top heavy and may become unbalanced.
- Verify that the capacity of the handling equipment is adequate for the transformer weight.
- Stabilize the transformer with a safety strap to reduce the possibility of tipping.
- Keep all unnecessary personnel away while handling and moving the transformer.

Failure to follow these instructions will result in death or serious injury.

Figure 5: Handling Using a Forklift

Towing and Moving

After the transformer has been off loaded, moving the transformer into position by a crane is preferred. When a crane cannot be used, the transformer can be skidded or moved on rollers. When doing so, take extra care not to damage the transformer.

The enclosure is a “bolt-together” design. If necessary, the enclosure can be disassembled to facilitate installation.

NOTE: Any disassembly and reassembly of the enclosure will be the sole responsibility of the owner and may void the warranty. Contact Schneider Electric for more information.

Storing

If the transformer must be stored, it is preferable to locate it in its permanent location on a concrete pad. If a level concrete surface is not available, take precautions to keep the unit from contacting an earthen surface. Protect the transformer and the connection points from the environment. Store an indoor unit indoors only. Maintain adequate ventilation so that air can flow through the transformer enclosure.

To reduce condensation and avoid moisture absorption in the transformer while it is being stored, immediately install space heaters, incandescent lamps, other small electric heaters. See “Drying the Core and Coil Assembly” on page 16 for more information.

© 1999–2005 Schneider Electric All Rights Reserved

If the transformer is stored for an extended time, make periodic inspections of the transformer exterior and interior for corrosion or other possible damage. Always make an internal inspection before the transformer is placed in service. If you have any concerns, contact Schneider Electric.

SECTION 4—INSTALLATION

NOTE: Complete start-up services are available from Square D Services. They can provide assistance in a variety of areas, from installation to comprehensive testing and verification of the new equipment. Contact Square D Services at 1-800-634-2003, 24-hours a day.

Transformer Location Indoor

Follow all local and national codes when locating the transformer. Make sure the ventilated openings, on the top and bottom of the enclosure, are clear. The transformer must be at least 12 inches (305 mm) from walls or other obstructions to allow circulation of air through and around each unit.

For indoor installations, consult local and national codes to ensure all applicable requirements are satisfied. If the transformer is located near combustible materials, make sure the transformer meets or exceeds the minimum clearances as required by the National Electrical Code® (NEC) or other applicable local codes.

Locate the transformer on a level foundation strong enough to support the weight of the transformer, preferably of reinforced concrete. The manufacturer recommends that you do not place the transformer directly on an earthen surface. Ensure the foundation has adequate drainage. Seismic regulations may require that the transformer be anchored to the pad.

Restricting Access to the Transformer

Ventilated dry type transformers are not designed or constructed to be tamperproof. Install the transformer in an area that is secure and that allows only authorized personnel access to the transformer.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

The transformer is not tamperproof, therefore restrict access to it. Allow only authorized personnel access to the transformer.

Failure to follow these instructions will result in death or serious injury.

Transformer Location Outdoor

For outdoor installations, consult local and national codes to ensure all applicable requirements are satisfied. If the transformer is located near combustible materials, make sure the transformer meets or exceeds the minimum clearances as required by the NEC or other applicable local codes. The transformer must be at least 12 inches (305 mm) from walls or other obstructions to allow circulation of air through and around each unit. Ventilated and nonventilated, outdoor substation transformers and pad-mounted unit substations are designed for installation on a well-drained, concrete pad. Unless specified otherwise, the transformer is supplied without a bottom plate in the enclosure. If installing the transformer in a elevated position where the bottom is exposed, add a bottom plate (for rodent resistance) with provisions for drainage to the enclosure.

© 1999–2005 Schneider Electric All Rights Reserved

Atmospheric Conditions

Atmospheric conditions and accessibility are important considerations when locating the transformer outdoors. Install outdoor ventilated transformers in locations that are free from unusual dust or chemical fumes.The enclosure helps protect the transformer from atmospheric conditions such as dust, rain, or snow. Also, the enclosure is designed to divert water from energized parts, insulation, and wiring. However, it may not protect against internal condensation or ice, or completely stop snow from entering. If possible, locate the transformer in a shielded area such as in the corner of a building or landscaped windbreak to provide extra protection from driving wind, rain, or snow. When subjected to severe weather, outdoor dry type transformers should be inspected to determine if added protection is necessary.

Accessibility

Outdoor pad-mounted enclosures have a hinged door on the low voltage compartment with a handle suitable for padlocking. Access to the high voltage is possible only after the low voltage door is opened, allowing authorized personnel access through a second door. Also consider accessibility for maintenance when locating the transformer. Installations where the transformer may be fully exposed to the public spaces, such as shopping centers or school yards may require additional precautions.

The pad-mounted enclosure design meets the ANSI and NEMA standard rod entry test to prevent the entrance of a rod having a diameter of 0.125 inch (3.175 mm) at any point on the enclosure. Ventilated enclosures have the same provisions as the nonventilated, except that the ventilated units have ventilation openings, which are designed according to the ANSI and NEMA standard rod entry test to prevent the entrance of a rod having a diameter of 0.500 inch (12.7 mm).

Cable Connections

When cable connections are required, conductors suitable for at least 194° F (90° C) should be used. Minimum clearance at terminals should be maintained in accordance with the following table.

Table 1: Terminal Clearances

Transformer BIL	Minimum Clearance (in.)
10	1.00
20	1.00
30	1.50
45	2.50
60	3.50
75	4.75
95	6.00
110	7.50
125	8.75
150	11.25
200	15.50

All connections should be made without placing undue stress on the terminals. Connectors should be securely fastened in place and adequately supported with allowances for expansion and contraction.

Lightning Arresters

At times, it becomes necessary to ship the specified lightning arresters loose to the job site due to physical size and/or to prevent damage. See Figure 6 for the typical installation method.

Figure 6: Installing Lightning Arresters

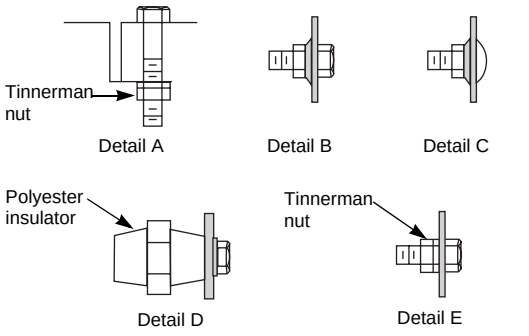
⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Low voltage on the transformer windings may exceed 600 V. Do not touch the windings.

Failure to follow these instructions will result in death or serious injury.

The transformer has both high voltage (HV) and low voltage (LV) winding connections. Multiple tap positions are available on the HV winding to allow for adjustments, which may be necessary because of the specific supply voltage or transformer load characteristics. If tap adjustments are necessary, see “Changing Tap Positions to Adjust Voltage” on page 20. Connection points are clearly labeled on the transformer. Refer to the nameplate and wiring diagram to make the electrical connections.



Follow these guidelines when making connections:

1. Clean the contact areas of the terminals (if applicable).
2. Use leads that are long enough to avoid mechanical strain caused by expansion and contraction. Strain can cause loose connections over time.
3. Using a torque wrench, ensure all bolted connections are torqued to the values given on the transformer label and in this bulletin. Refer to Table 2 on page 14 for torque information.

Electrical Connections for Pad-Mounted Transformers

Pad-mounted dry type transformers are provided with HV and LV terminals for primary and secondary connections. Multiple tap connections are available on the HV windings to allow for adjustments, which may be necessary because of the specific supply voltage or transformer load characteristics. If tap adjustments are necessary, see “Changing Tap Positions to Adjust Voltage” on page 20. Connection points are clearly labeled on the transformer. Refer to the nameplate and wiring diagram to make the electrical connections.

High Voltage Bushing Connections

Depending on the transformer specification, HV bushings are either live-front with exposed-metal terminals or molded dead-front (Figure 7).

Live Front: Lugs are required to terminate the cable on a live front bushing. If the live front design and shielded cable are used, install a cable stress relief terminator kit on each high voltage cable.

Dead Front: Install an elbow terminator kit on the cable to connect to the dead front bushing. On the dead-front design, the elbow terminator kit includes the necessary cable stress relief.

Contact the Square D Medium Voltage Transformer facility at 704-283-7411 for application or order information regarding live front or dead front terminator kits. Installation instructions are provided with the terminator kits. Elbow terminators and stress cones are not provided by the manufacturer.

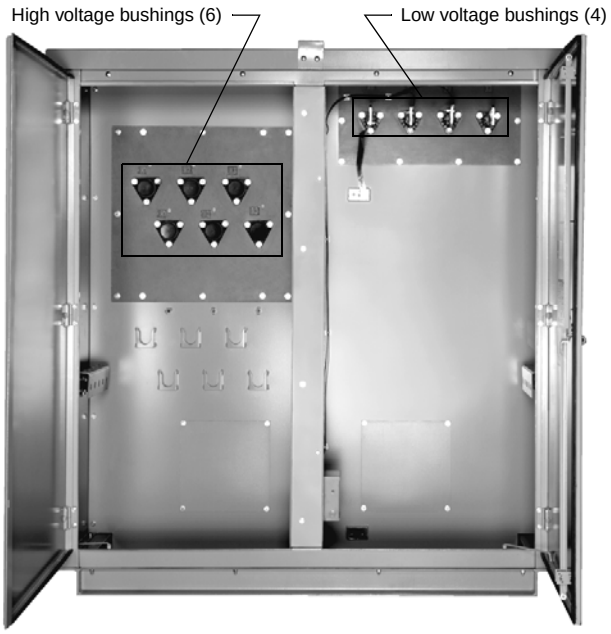
Universal Bushing Well
(requires a separate insert)

One-Piece Integrated Bushing
(well and insert molded in one-piece construction)

© 1999–2005 Schneider Electric All Rights Reserved

The one-piece integrated bushing is shipped with a red plastic protective cap to protect the internal bushing contact points from dirt or moisture. Leave this cap in place until the transformer is energized. When the transformer is energized, plug the ground cap onto any unused bushing well or insert to avoid partial discharge and subsequent bushing damage.



The transformer nameplate (Figure 2 on page 8) illustrates the internal wiring and external marking of each bushing. Refer to the nameplate on the transformer for clarity on where to connect each incoming cable.

On live front designs, ensure that adequate air clearances are between all energized parts in accordance with the latest ANSI Standard C57.12.22.

Low Voltage Bushing Connections

Low voltage terminals through 600 V are supplied with NEMA standard hole drillings and spacings, but are not supplied with lugs. Lugs may be stacked or mounted on either face of the spade. For 600 V bushings only, maintain a minimum of one inch air clearance between phase to phase or phase to ground.

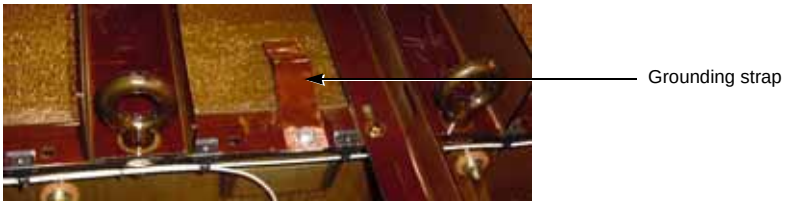


Figure 8: Typical Locations for Bushings on Pad Mounted Dry Type

Grounding

To ground the transformer, use only the ground pads on the base of the transformer. Do not use hold-down bolts or cleats, or any other component to establish the transformer ground.

Figure 9: Core Ground Strap Location

ENGLISH

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- When grounding the transformer, conform to all applicable codes. Improper grounding can cause high voltage on the transformer secondary terminals.
- Secondary voltages may reach supply voltage levels. Under certain fault conditions, the secondary voltages from line to ground of transformers with ungrounded secondary windings (such as delta, floating wye and open delta) may approach a level as high as the supply voltage. DO NOT TOUCH THE WINDINGS.
- Before servicing the transformer, ensure all static charge has been discharged by grounding the coils with an appropriate grounding device.

Failure to follow these instructions will result in death or serious injury.

SECTION 5—START-UP TESTING

NOTE: Complete start-up services are available from Square D Services. They can provide assistance in a variety of areas, from installation to comprehensive testing and verification of the new equipment. Contact Square D Services at 1-800-634-2003, 24-hours a day.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Only qualified personnel should perform these tests.
- Disconnect ALL high voltage, low voltage, and neutral connections.
- Disconnect auxiliary equipment such as lightning arresters, the fan and temperature control system, meters, or any other low voltage control system that is connected to the windings that are involved in these tests.
- DO NOT disconnect the ground connection to the transformer frame.

Failure to follow these instructions will result in death or serious injury.

Before energizing the transformer and placing it in service, the manufacturer recommends that the following tests be performed at the installation site:

- **Insulation Resistance:** Measures the resistance of the insulation between the primary and secondary windings and from each winding to ground.
- **Turns Ratio:** Measures the ratio of the primary to secondary turns to check for possible insulation degradation in the windings.
- **Core Megger® Test**: Measures the resistance to the flow of current through and over the surface of the transformer insulation. Results can indicate possible insulation deterioration. Applicable for units ordered with an isolated core only.

Drying the Core and Coil Assembly

If the transformer is to be held in storage or will undergo periods of de-energization, it is recommended that space heaters be used to prevent accumulation of moisture on the core and coil assembly. The space heaters are typically 120 volt/50 watt and are usually thermostatically controlled. Heaters are mounted directly beneath the coils, front and back, on brackets attached to the bottom core clamps and mounting feet. Two heaters are used per coil, with three heaters on the high-voltage side and three on the

© 1999–2005 Schneider Electric All Rights Reserved

low-voltage side. Space heaters are provided with a terminal block for connection to an external power source.

Using the Insulation Resistance Test to Determine Drying Time

The transformer core and coils must be dry before the transformer can be tested and energized. If the transformer has more than surface moisture present, more extensive drying may be required to ensure that the core and coils are dry. To dry the transformer, apply external heat to the transformer using the heater or lamp method described above. For transformers without an enclosure, the core and coil assembly can also be placed in a suitably ventilated oven.

Drying time depends on the condition of the transformer, size, voltage, amount of moisture absorbed, and method of drying. Measuring insulation resistance is valuable in determining the drying status.

Normal humidity has little effect on energized dry type transformers. If a shutdown occurs during a period of low humidity, no special precautions are necessary before re-energizing the transformer.

However, under conditions of high humidity, take precautions to ensure there is no condensation inside the transformer. Space heaters (optional) placed inside the housing should be energized to provide protection against this condition. As a simple rule, always keep the transformer a few degrees above the ambient temperature.

⚠ CAUTION

FIRE HAZARD

Constant attendance during the drying process is recommended. Have a suitable fire extinguisher on hand for use in the event of an emergency.

Failure to follow this instruction can result in injury or equipment damage.

Drying

To remove moisture from a transformer that has been exposed to high humidity, spray, or extended storage, the following methods are recommended:

1. **Applications of external heat**
   External heat is applied by passing heated air through the inlets in the bottom of the transformer housing. Direct the air so that it passes through the winding ducts and not only around the sides of the coils. Adequate ventilation is essential during this process. The most effective way to apply external heat is to place the core and coil assembly into a well ventilated oven.
2. **Heating by circulation of current**
   Heating by circulation of current is accomplished by short circuiting the secondary terminals of the transformer and applying impedance voltage to the primary terminals. This will produce 100% rated current in all windings. To obtain the impedance voltage, multiply the “per unit” value of the nameplate % impedance by the primary voltage noted on the nameplate. For example, for 13,800 volts with 5.75% impedance, multiply 0.0575 x 13,800 = 794 volts.

The heating process should be continued until an insulation test gives satisfactory results. In no case should the windings exceed 302° F (150° C) at the hottest measurable spot while applying the circulating current method.

© 1999–2005 Schneider Electric All Rights Reserved

Use of Insulation Resistance for Determining Drying Time

Drying time depends on the condition of the transformer, size, voltage, amount of moisture absorbed and the method of drying used.

The measurement of insulation resistance is a value in determining the status of drying. Take measurements before starting the drying process and at two hour intervals during drying. The initial value, if taken at ambient temperature, may be high even though the insulation may not be dry. Keep the temperature of the transformer constant during the drying period to obtrain comparative readings.

As the transformer is heated, the presence of moisture will be evident by the rapid drop in resistance measurements. Following this period, the insulation resistance will generally increase gradually until near the end of the drying period when it will increase more rapidly. Sometimes it will rise and fall through a short range before steadying, because moisture in the interior of the insulation is working out through the initially dried portions. A curve with the time as abscissa and resistance as ordinate can be plotted. Continue the drying until the resistance levels off and remains relatively constant for three to four hours.

Before taking resistance measurements, the transformer should be de-energized and the winding should be short circuited and grounded for at least one minute to drain any static charge. All readings should be taken at the same time of application of the test voltage, preferably one minute.

Insulation resistance measurements should be taken in this order:

1. Primary to ground with secondary grounded.
2. Secondary to ground with primary grounded.
3. Primary and secondary to ground.

If winding resistance is used in determining winding temperature, contact the factory to obtain the needed information.

Insulation Resistance Testing

Before performing the insulation resistance test, use a vacuum cleaner to clean the core and coil assembly. When measured in accordance with ANSI/IEEE Standard C57.94, the minimum insulation resistance should be as listed in Table 3:

Table 3: Insulation Resistance Values

Winding kV Class	Insulation Resistance (MΩ)
1.2	600
2.5	1000
5.0	1500
8.7	2000
15.0	3000

Turns Ratio Test

Perform the turns ratio test at each tap position and for the full winding.

1. Use a Transformer Turns Ratio (TTR) to measure the ratio between the primary and secondary windings.
2. Compare these measurements to the transformer nameplate voltage ratio. The measurements should be within 1/2 of 1% of the nameplate voltage ratio. Refer to ANSI C57.12.91 for additional information.

Core Megger® Test

The core of a ventilated dry type transformer is constructed using one of two methods. For standard construction, the core is not insulated from the clamping structure. The core and clamping structure are at the same potential. In this case, the core Megger test is not applicable.

© 1999–2005 Schneider Electric All Rights Reserved

When specified, the transformer core is totally isolated from the core clamping structure by a layer of insulation. The core does not make contact with the clamping structure. A core ground strap is inserted between the laminations to ground the core to the clamping structure. A core Megger test can be performed to measure the resistance of the flow of current through and over the surface of the transformer insulation.

Before the core Megger test can be performed, inspect the transformer. The copper-foil ground strap extends out from the top of the core and attaches to the top core clamp. Follow these steps to perform the core Megger test:

1. Obtain a 1000 V megohmmeter.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Read and understand the equipment manufacturer's instructions. Use caution while operating the megohmmeter.

Failure to follow these instructions will result in death or serious injury.

2. Disconnect the core ground strap from the core clamp. Make sure the ground strap is clear from any contact with the transformer ground to isolate the clamp structure.
3. Taking care not to pull the core ground strap out of the core, attach the hot lead of the megohmmeter to the core ground strap.
4. Attach the ground lead of the megohmmeter to the core clamping bolt, which is next to the core ground strap. Ensure the lead and core ground strap are not in contact with the ground.
5. Energize the megohmmeter.

   NOTE: A reading of 10 megohms or greater is acceptable. If the reading is less than 10 megohms, contact Square D Services at 1-800-634-2003.
6. Reattach the core ground strap to the core clamp.

SECTION 6—OPERATION

Energizing the Transformer

Before energizing the transformer, do the following:

1. Remove all shipping braces and shipping bolts (if present). They are clearly tagged or painted yellow.

   NOTE: DO NOT remove the fiberglass tubing (if provided) that surrounds the high voltage cables.
2. Verify the operation of fans, motors, controllers, relays, or other auxiliary devices.
3. Verify the selection of taps and ratio connections against the transformer nameplate information.
4. Torque all connections according to the torque guidelines in Table 2 on page 14 and ensure clearances are adequate between the transformer enclosure and internal bus bars.
5. Remove all hand tools, equipment, or any other foreign material from inside the enclosure. **Do not** leave tools or other equipment on the core and coil assembly.
6. Energize the transformer.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Only qualified personnel with appropriate measurement devices should measure the voltages on the transformer.

Failure to follow these instructions will result in death or serious injury.

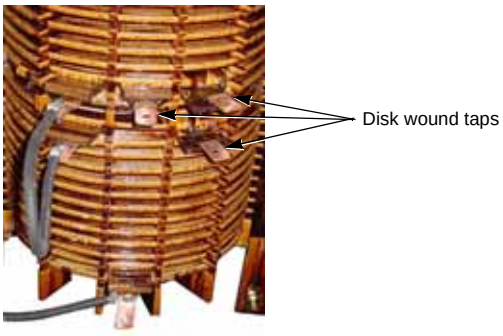
7. Check the transformer nameplate before measuring voltages and ensure that properly rated meters are used to verify the primary and secondary transformer voltages.
8. Verify the voltages on the transformer primary and secondary.

If the voltages are not as required, use the taps to adjust the voltage. See the following section, “Changing Tap Positions to Adjust Voltage”.

Changing Tap Positions to Adjust Voltage

To change the tap position:

⚠ DANGER



HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Before performing this procedure, review “Section 2—Safety Precautions” on page 6.
- Do not change the tap connections when the transformer is energized.
- Disconnect all power and verify the transformer is de-energized before servicing the transformer. Use a properly rated meter to measure for the presence of voltage at the terminal and to verify the transformer is de-energized. Do not rely on visual indications such as switch position or fuse removal for determining a de-energized condition.
- Ensure no paths are present for backfeeding power to the transformer (such as through a tie-breaker).

Failure to follow these instructions will result in death or serious injury.

NOTE: Do not bend or position the hardware in a manner that would reduce clearance between tap terminals.

Figure 10: Disk Wound Tap Connections

1. De-energize the transformer following the safety messages above and your company’s lock-out/tag-out procedures.
2. Remove the enclosure panel or door to access the transformer high voltage windings.
3. Use an appropriate grounding device to ground the coils and discharge any static charge.
4. Locate the tap jumpers.
5. Change the tap jumpers on each phase to the appropriate tap connection (Figure 10). The tap jumpers must be on the same tap position for each phase.
6. Torque the tap connections. Refer to the torque values in Table 2 on page 14.

   NOTE: For multiple voltages or other special arrangements, see the transformer nameplate.
7. Inspect the enclosure to ensure all hand tools, equipment, or any other foreign materials are removed from the enclosure.

© 1999–2005 Schneider Electric All Rights Reserved

8. Re-install the door or enclosure panel.
9. Energize the transformer.

Sound Level

All transformers have an inherent sound level that varies with the size of the units. The fundamental frequency is twice that of the applied voltage.

Sound waves may be amplified by means of reflected waves and/or radiated waves via walls, floors, ceilings, mechanical vibrations of air ducts, conduits, and mounting bases. For average expected sound levels, refer to NEMA ST-20.

To meet NEMA listed average sound levels, each unit should be installed in a location where there is a 10-foot clearance on all sides except floor or ground. Units located in close proximity to hard surfaces may produce higher than average sound levels. When transformers must be located in noise sensitive areas, precautions should be taken to avoid amplification of the transformer sound.

Install the unit in an area where the noise will be least objectionable. Avoid rooms where hard surfaces are in close proximity to the transformer.

Use acoustic absorbing materials on walls, floors, and ceilings. Avoid installation of units in corners, hallways, and stairways, and near heating and air conditioning ducts.

Reduction of Structure Borne Noise

Loosen anchor bolts between the transformer and enclosure and let the unit rest on the vibration pads only. (Except on certified seismic units.)

Use flexible conduit and bus connections.

Avoid mounting the unit on walls, balconies, and floors with low masses. Avoid uneven mounting surfaces. If specified, low sound level transformers can be provided for most applications.

SECTION 7—MAINTENANCE

Complete start-up services are available from Square D Services. They can provide assistance in a variety of areas, from installation to comprehensive testing and verification of the new equipment. Contact Square D Services at 1-800-634-2003, 24-hours a day.

Inspect the transformer regularly. The frequency of inspection depends on operating conditions. If the transformer is operating in usual service conditions as defined in ANSI/IEEE C57.12.01, an inspection every two years may be sufficient. However, for unusual locations where the air is contaminated with particles such as dust or chemical fumes, inspect the transformer every three months or sooner. After the first few inspections, determine a more definite schedule based on the existing conditions. Perform the following procedures for maintenance.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Before performing this procedure, review “Section 2—Safety Precautions” on page 6.
- Before servicing the transformer, ensure all static charge has been discharged by grounding the coils with an appropriate grounding device.

Failure to follow these instructions will result in death or serious injury.

© 1999–2005 Schneider Electric All Rights Reserved

1. De-energize the transformer following the preceding safety messages and your facility's lock-out /tag-out procedures.
2. Ground unit for one minute to drain static charge.
3. Clear away any debris or other foreign objects from all ventilation openings. If the transformer design includes an optional solid base, make sure air can flow through the bottom grills of the enclosure.
4. Remove the enclosure panel or door to access the transformer high voltage windings.
5. Check the enclosure for deterioration. If deterioration is present, determine the cause and correct (if possible). Repaint deteriorated areas.
6. Replace corroded hardware, as required. See "Replacement Parts" on page 24.
7. Ensure all interior surfaces are clean by following the procedure in "Cleaning" below.
8. Inspect safety labels and replace as necessary.
9. See "Energizing the Transformer" on page 19 to power up the transformer.

After a Major Fault

1. If the transformer is energized, de-energize the transformer following the safety messages above and your facility's lock-out/tag-out procedures.
2. Remove the enclosure panels and inspect the transformer core and coil assembly for any physical damage. If damage has occurred, contact the Square D Medium Voltage Transformer facility at 704-283-7411.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Do not re-energize the transformer if the transformer has been damaged.

Failure to follow these instructions will result in death or serious injury.

3. Using a torque wrench, ensure all bolted connections are torqued according to the torque guidelines in Table 2 on page 14.
4. Perform the tests described in "Section 5—Start-Up Testing" on page 16. DO NOT re-energize the transformer if the test results are not acceptable. If no damage has occurred and all test results are acceptable, perform maintenance by following the procedures in "Section 7—Maintenance" on page 21.

Cleaning

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Before performing this procedure, review "Section 2—Safety Precautions" on page 6.
- Before servicing the transformer, ensure all static charge has been discharged by grounding the coils with an appropriate grounding device.

Failure to follow these instructions will result in death or serious injury.

© 1999–2005 Schneider Electric All Rights Reserved

To clean the transformer, do the following:

1. De-energize the transformer following the safety messages above and your facility's lock-out/tag-out procedures.
2. Ground unit for one minute to drain static charge.
3. Remove the enclosure panel or door to access the transformer high voltage windings.

⚠ CAUTION

HAZARD OF EQUIPMENT DAMAGE

Do not push or pull the cloth through the coils.

Failure to follow this precaution can result in injury or equipment damage.

4. Wipe down all parts of the core, being careful not to cut yourself on any sharp edges or protrusions.
5. Use an industrial vacuum cleaner to clean the ventilation openings and remove dirt and dust from the core, coils, insulators, and remaining structures.
6. Remove all rags or other maintenance equipment from the coil ducts and check for tools when finished. Confirm that the coil ducts are clear.

SECTION 8—OPTIONAL EQUIPMENT

This section provides information about optional equipment and replacement parts.

Temperature Monitoring Systems

Optional temperature control modules are available on ventilated dry type transformers.The monitor controls the fans and provides alarm indication. See the manufacturer's instruction manual included with the transformer documentation package for detailed information about the installation, operation, and maintenance of the monitor.

The factory pre-set temperature alarm and control settings for ventilated transformers are listed in Table 4.

Table 4: Factory-Set Temperature Alarm and Control Settings

Stage	Temperature Rise
	Transformers with 80 °C / 150 °C Temperature Rise Rating

Neutral Grounding Resistors

If specified, optional neutral grounding resistors may be supplied. See the manufacturer's instruction manual included with the transformer documentation package for detailed information about the resistors.

Other Optional Equipment

Other optional equipment, such as monitors, current or potential transformers, or space heaters, may be supplied if specified.

Replacement Parts

Some replacement parts for the transformer are available. Contact your Schneider Electric field sales representative for price and availability. Provide full nameplate information and a description of the part needed. Sketches or photographs may be useful in describing the part.

SECTION 9— TROUBLESHOOTING

If any of the problems listed in Table 5 are identified, the transformer should be removed from service at once. Immediate attention to the problem may prevent dangerous conditions or expensive repairs. In many instances, the trouble can be found quickly and the unit returned to service.

If the trouble cannot be corrected, do not re-energize the transformer. Contact the factory immediately.

Further inspection may require disassembly of the core and coils. This work must be performed by a factory representative or authorized repair facility.

Table 5: Troubleshooting Guide

Circuit	Symptom	Cause
Electric	Overheating	Continuous overload; wrong external connections; poor ventilation; high surrounding air temperature [a]; damaged or improperly directed fan blades; high harmonic or unbalanced loads
	Reduced or zero voltage	Shorted turns; loose primary tap connections
	Excess secondary voltage	High input voltage; improper primary tap connections
	Unbalanced secondary voltages	Overload; tap connections not on identical tap positions; neutral ungrounded
	Insulation failure	Continuous overloads; dirt accumulation on coils; mechanical damage in handling; lightning or switching surges
	Breakers or fuses opening	Short circuit; overload
	Excessive cable heating	Improperly bolted connection; incorrect cable size for load; incorrect cable routing
	High voltage to ground [b]	Usually a static charge condition
Magnetic	Vibration and noise	Low frequency; high input voltage; core clamps loosened in shipment/handling; improper tap connection
	Overheating	High input voltage; improper loads; harmonics; dirty core
	High exciting current	Low frequency; high input voltage; shorted turns
Dielectric	Smoke	Insulation failure
	Burned insulation	Lightning surge; switching/line disturbance; broken bushings, taps, or arresters; excess dirt or dust on coils
	Overheating	Clogged air ducts or inadequate ventilation
	Breakers or fuses opening	Insulation failure

Hazard Categories and Special Symbols

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates an electrical hazard exists that will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to potential personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates an imminently hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a potentially hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a potentially hazardous situation which, if not avoided, **can result in** minor or moderate injury.

CAUTION

CAUTION, used without the safety alert symbol, indicates a potentially hazardous situation which, if not avoided, **can result in** property damage.

NOTE: Provides additional information to clarify or simplify a procedure.

Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

Introduction

The Model 98A digital temperature controller can continuously monitor up to three Type K thermocouples in the windings of a dry type transformer. Based on winding temperatures, the controller has the capability to perform the following functions.

- The controller can display the current winding temperature of each phase. It also stores and displays the highest phase temperature, identifying which phase caused that high temperature.
- The controller can operate relays that activate the fans or blowers, sound the high temperature alarm, or actuate a high temperature trip. The controller compares the highest of the three phase temperatures to temperature set points that are stored in the controller's memory. These set points can be reviewed from the controller.
- The default state of the Alarm relay is normally energized so that the alarm sounds upon power failure (fail-safe). The default state of all other relays is normally de-energized (non-fail-safe).
- An internal audible device (buzzer) sounds when the alarm is ON. The audible device can be silenced using the Front Panel Silence button without changing the state of the Alarm relay.
- Two auxiliary relays with non-energized default states are available.
- A Fan Exerciser circuit turns the fans ON for one minute every seven days.
- The controller can interface as part of a complete PowerLogic™ power monitoring and control system manufactured by Schneider Electric. The controller can transfer real-time information to the PowerLogic system about the winding temperatures, status of the relays, and the temperature set points contained within the controller's memory. Once in the PowerLogic system, the information can be used in tables, graphs, and reports.
- The controller can be tested to check its operation at any time. However, the controller continuously performs internal checks and will display error codes if a problem with its operation is detected.

Table 1 shows the outputs from the controller. For details about the functionality of the controller, see "Operation" on page 13.

NOTE: This instruction bulletin is not an application guide for the Model 98A controller or a substitute for adequate training in safe working procedures for this and related electrical equipment. Installation of this electrical equipment may require special licenses or training. Consult applicable national, industry, and local codes for specific requirements that may apply.

The successful operation of this device depends on various factors such as installation, service conditions, and maintenance. Unless designed for other specific applications, this device should be installed on a transformer that is operating under the conditions specified in IEEE C57.12.01.

NOTE: If additional information is needed that is not covered by this instruction bulletin, contact your local Schneider Electric representative.

Safety Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- Read and understand this entire instruction bulletin before operating or maintaining the Model 98A Digital Temperature Controller. Also read and understand the bulletin that ships with the transformer before installing, operating, or maintaining a dry type transformer. Follow all applicable local and national codes.
- The controller is designed to be operated and maintained while the transformer is energized. However, many parts of the transformer operate at high voltages. DO NOT TOUCH any transformer parts. Use only electrically insulated tools when working around electrical equipment.
- Disconnect all power and verify the transformer is de-energized before servicing the transformer. Operation of a primary protective device may be evidence of a faulted transformer. Do not re-energize the transformer until the cause of operation of the primary protective device is found and corrected.
- Do not rely on visual indications such as switch position or fuse removal for determining a de-energized condition. Always assume that a terminal is energized unless it is checked with a properly rated meter to ensure the terminal is de-energized and grounded.

Failure to follow these instructions will result in death or serious injury.

Installation

The Model 98A controller is installed on the transformer at the factory when the transformer is ordered with a forced air cooling package, with provisions for future air cooling (package without fans), or with provisions for transformer monitoring only.

NOTE: Any disassembly and reassembly of the enclosure or any other part of the transformer will be the sole responsibility of the owner and may void the warranty. Square D Services is available to ensure a factory-authorized installation of the controller.

The Model 98A controller is factory installed in a control box that allows access to the controller without de-energizing the transformer. Do not energize the transformer if the box has been tampered with or removed.

The control box provides additional user safety and shields the controller from free flowing air currents, such as those caused when the fans turn on. Moving air could cause the controller to report incorrect readings.

If the controller has been purchased separately and has not been factory installed, contact Square D Services for recommended installation instructions.

Connections

The type of connection required depends on the use of the controller.

- **Power connections**—If the controller is factory installed without self-contained power, two power connections are required: one for control power and one for fan power. All other wiring is completed at the transformer manufacturing facility.
- **Remote monitoring connections**—If the controller is being used with a remote display and remote alarm, the controller must be wired for this use.
- **PowerLogic system connections**—If the controller is part of a PowerLogic power monitoring and control system, the controller must be connected to the PowerLogic system.

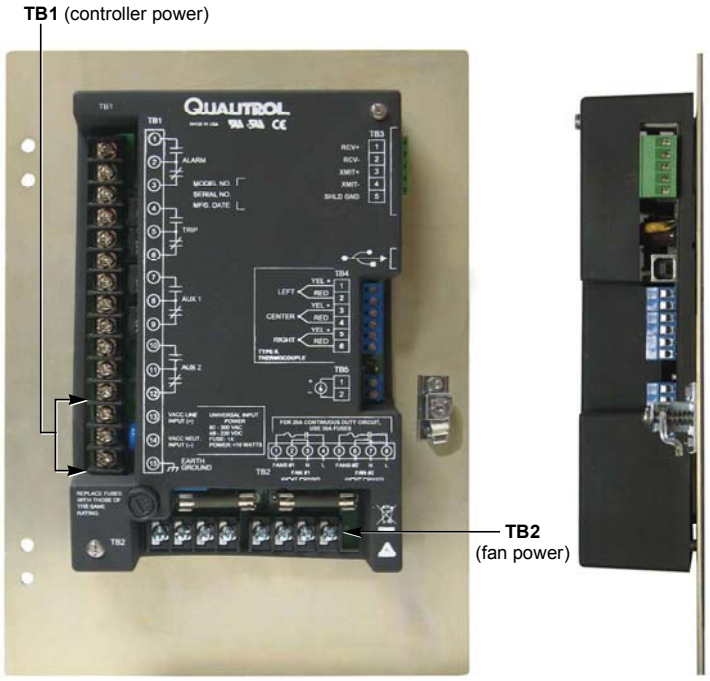
ENGLISH

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Review “Safety Precautions” on page 6 before making any connections.
- Ensure all personnel, tools, controller wiring, and other work material or equipment are cleared from the transformer and the control box before turning ON power to the controller.



Failure to follow these instructions will result in death or serious injury.

Connecting to the Power Source

The Model 98A controller is equipped with a universal power supply (UPS) that can accept 80–300 Vac, 50/60 Hz or 48–220 Vdc to power the controller only. If the transformer is provided with a self-contained power supply, the power supply is factory-wired. When an external power supply is provided, see the wiring diagram provided with the transformer for power supply connections.

The power supply for the fans or blowers is factory-wired if the transformer is provided with a self-contained power supply. When an external power supply is provided, see the wiring diagram provided with the transformer for power supply connections.

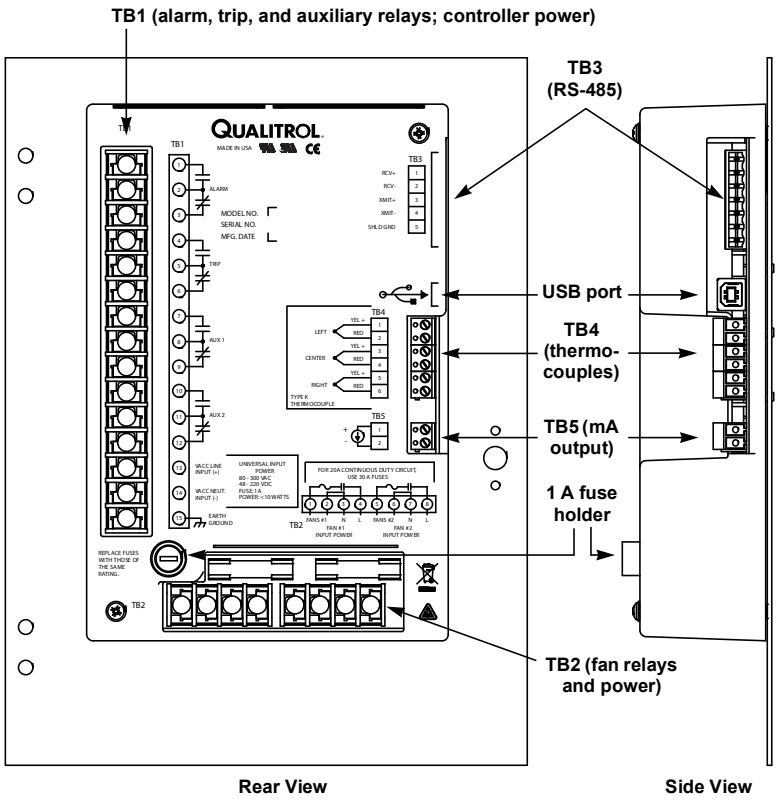
⚠ CAUTION

HAZARD OF EQUIPMENT DAMAGE

Before applying power, make sure all personnel and equipment are clear of the fans or blowers.

Failure to follow these instructions can result in injury or equipment damage.



When the controller is powered on, the fans or blowers turn ON and then, after approximately one minute, OFF. This can be used as an initial test to ensure all fans or blowers are operating.

A 5 x 20 mm, 1 A, Type F fuse located in the round fuse holder on the back cover protects the controller. If the fuse blows, make sure the power input voltage connections have been properly made.

Do not replace and re-energize the controller until the situation is corrected. If it is determined that the controller is properly connected, ensure that all power is off, replace the fuse, and re-energize the controller. If the situation cannot be corrected, contact the Schneider Electric Customer Information Center at 1-888-778-2733, or send an e-mail to monroe-after-shipment@us.schneider-electric.com.

All other connections are pre-wired at the transformer facility. Table 2 on page 10 shows the pre-wired connections.

Figure 2: Wiring Terminals/Connectors

ENGLISH

⚠ CAUTION

HAZARD OF EQUIPMENT DAMAGE

The transformer may not operate as designed if the fan, alarm, or trip settings are changed. Only an authorized Schneider Electric representative can make set point changes to the controller. If changes to the factory settings are needed, contact the Schneider Electric Customer Information Center at 1-888-778-2733, or send an e-mail to monroe-after-shipment@us.schneider-electric.com.

Failure to follow this instruction can result in injury or equipment damage.

Table 2: Factory Pre-wired Connections

Connection Type	Controller Terminal	Description	Connection Information
Thermocouples	TB4-1 to TB4-2	Thermocouple sensor #1 (left phase)	Type K thermocouples are standard. The yellow lead is connected to the positive terminal (1, 3, or 5) and the red lead is connected to the negative terminal (2, 4, or 6).
	TB4-3 to TB4-4	Thermocouple sensor #2 (center phase)	
	TB4-5 to TB4-6	Thermocouple sensor #3 (right phase)	
mA output	TB5-1, 2	Milliampere output current loop	Provides a current proportional to the present highest temperature. TB5-1 is the positive terminal.
Controller power	TB1-13, 14, 15	Universal power supply 80–300 Vac, 50/60 Hz or 48–220 Vdc	Required only if the transformer is not provided with a self-contained power supply.
Fan power	TB2-3, 4, 7, 8	Fan voltage	
Relay contacts	TB2-1, 2	Fan #1 controls the fans or blowers through a fuse.	Each fan circuit is protected by its own fuse and controlled by a separate relay with a SPST Form A contact.The contact is open when no power is applied to the unit. The alarm, trip, and auxiliary relay contacts are SPDT Form C. The alarm relay is normally energized and changes state when power is lost. The trip and auxiliary relays are normally de-energized and do not change state when power is lost.
	TB2-5, 6	Fan #2 controls the fans or blowers through a fuse. The Fan #2 circuit is electrically separate from the Fan #1 circuit.	
	TB1-1, 2, 3	Alarm—SPDT (Form C) contacts at TB1-1, 2, and 3 indicate an alarm condition. This relay is usually set to be energized in the normal state so that the loss of control power will cause an alarm.	
	TB1-4, 5, 6	Trip—SPDT (Form C) contacts at TB1-4, 5, and 6 indicate that the temperature being monitored has reached the trip state. This relay is usually set to be de-energized in the off state.	
	TB1-7, 8, 9	Auxiliary 1—SPDT (Form C) contacts at TB1-7, 8, and 9	
	TB1-10, 11, 12	Auxiliary 2—SPDT (Form C) contacts at TB1-10, 11, and 12	

Connecting to Remote Current Loop Output

The temperature controller provides a milliampere analog signal for use with remote meter or SCADA systems. Access this output on TB5 terminals 1 (+) and 2 (-). The output is preset at 4–20 mA.

USB Link

A USB data link is used by the factory to install the standard configuration. A USB plug is provided for this link.

NOTE: Connect a USB cable only when a configuration update is required. No permanent wires should be attached to this connector.

Communications Wiring

The Model 98A controller is equipped with an RS-485 communication port. The RS-485 standard allows daisy chaining up to 32 devices on a single communications link.

A five-terminal connector on the side of the controller (Figure 3) provides a four-wire, RS-485 connection when wired as shown in Table 3. Connect terminals 1 and 3 and terminals 2 and 4 to create a 2-wire network.

The controller can be connected to the serial communication port of any Modbus™ master device, such as a PowerLogic EGX Ethernet gateway.

To daisy chain the Model 98A with other Modbus RTU-compatible devices, use a shielded communications cable containing one twisted pair for 2-wire networking or two twisted pairs for 4-wire networking. For example, use a Belden 9841 or equivalent cable for 2-wire networking or a Belden 9842 or equivalent cable for 4-wire networking. See Table 3 for the RS-485 terminal block connector designations.

The Model 98A controller is designed to interface with the PowerLogic power monitoring and control system from Schneider Electric using the Modbus RTU protocol. All communication setup functions that are normally performed at the controller can be performed remotely via a PC.

To set the parameters for the RS-485 connection, see “Communications Setup” on page 12.

Communications Setup

The communications setup of the Model 98A controller can be changed from the front panel by the following procedure:

1. Press and hold all three buttons until the unit stops cycling through the readings (approximately ten seconds).

   The controller then displays the current baud rate. See Table 4.

Table 4: Baud Rates

Display	Bits per Second
12	1200
24	2400
48	4800
96	9600
192	19,200

   Pressing the SILENCE/TEST (top) button will step the display **up** through the baud rate choices shown in Table 4. Pressing the MANUAL/AUTO (bottom) button will step the display **down** through the choices.

2. When the desired baud rate is displayed, press the RESET (middle) button.

   The display then shows the current parity setting:

Table 5: Parity Settings

Display	Description
PE	Even parity (standard)
PO	Odd parity
P--	No parity

3. When the desired parity is displayed, press the RESET (middle) button.

   The display then shows the current stop-bit setting.

   If parity is even or odd, the display will show S1 and cannot be changed.

   If no parity has been selected, the number of stop bits can be set to 1 or 2 (S1 or S2). S1 is used if the unit is communicating through a modem; otherwise, S2 is standard.

4. When the desired stop bit is displayed, press the RESET (middle) button. The display shows the current address setting.

   Pressing the SILENCE/TEST (top) button will step the display **up** through the addresses. Pressing the MANUAL/AUTO (bottom) button will step the display **down** through the addresses.

   NOTE: Legal Modbus addresses are 1-255.

5. Press the RESET (middle) button to return the controller to normal operation and save the settings. If a button is not pressed for 30 seconds, the unit will automatically return to normal operation and the communications setup will be unchanged.

Operation

The front panel of the Model 98A controller displays transformer temperature data, communicates the state of the outputs, and allows review of the set points. It is also possible to control the fans and alarm, and reset the maximum temperature setting using the buttons on the front panel.

Output Relay Status LEDs

Figure 4: Front Panel Detail

Five LEDs indicate the status of the output relays:

- The yellow FANS LED illuminates when the fan relay is activated. This is triggered when the transformer temperature is above the temperature set point of the fan relay.
- The red ALARM LED indicates that the alarm relay is in the alarm state when the alarm temperature set point is exceeded.
- The red TRIP LED indicates that the trip relay is in the trip state when the maximum temperature set point is exceeded. The trip relay provides a contact that can be used to take the transformer off line.
- The red AUX1 LED indicates that the first auxiliary relay is in the active state.
- The red AUX2 LED indicates that the second auxiliary relay is in the active state.

Temperature Display

The temperature display (Figure 5) consists of a three-digit, seven-segment, back-lit LCD display that can show temperatures from 0–250 °C and four individual icons that identify the temperature being displayed. The display shows each reading for approximately one second and then automatically steps to the next reading.

During normal operation, the display cycles through the three winding temperatures and the single highest temperature recorded. While the maximum stored temperature is displayed, both the MAX icon and the icon representing the winding that caused the maximum reading turn ON. The maximum temperature can be reset at any time (see “Resetting the Maximum Stored Temperature” on page 15). See “Thermocouples and the Temperature Display” on page 17 for technical details about the temperature readings.

Figure 5: Temperature Display

Manually Controlling the Fans or Blowers

Pressing the MANUAL/AUTO button manually activates the fan relay and turns the fans or blowers ON. The yellow FANS LED illuminates to show that the fans are ON and the Manual Fan icon (MAN) displays to show that the fan function is in manual mode.

When the fan function is in manual mode, pressing the MANUAL/AUTO button returns the function to automatic mode. If the temperature is below the set point that activates the fans, the fans will turn OFF and the yellow FANS LED and the Manual Fan icon (MAN) will no longer be displayed. However, if the temperature is above the set point, the Manual Fan icon (MAN) will no longer be displayed, but the fans or blowers and the FANS LED will remain ON until the temperature falls below the set point.

You can press the MANUAL/AUTO button any time to verify that the fan relay and the fans or blowers are operating properly.

Silencing the Alarm

Whenever an alarm is activated, an internal buzzer sounds and the ALARM LED illuminates. To silence the buzzer, press the SILENCE/TEST button. The buzzer remains off until a new alarm occurs. The ALARM LED remains illuminated until the temperature drops below the set point or the problem has been corrected. Silencing the buzzer does not eliminate the problem that caused the alarm. Promptly find and correct the situation that caused it.

If the buzzer sounds but the ALARM LED is not illuminated, check the 1 A fuse located in the round fuse holder on the back cover.

© 1999–2011 Schneider Electric All Rights Reserved

Reviewing Set Points

When the alarm is not sounding, pressing the SILENCE/TEST button starts a test sequence to verify that the controller is operating properly and allows a review of the set points. The test sequence performs the following checks at two-second intervals:

1. Displays the FAN ON temperature set point and lights the FANS LED.
2. Displays the ALARM temperature set point and lights the ALARM LED.
3. Displays the TRIP temperature set point, and lights the TRIP LED.
4. Displays the AUX1 temperature set point and lights the AUX1 LED.
5. Displays the AUX2 temperature set point and lights the AUX2 LED.
6. Displays the ambient temperature inside the controller.
7. Displays 888 on the temperature display, turns on all icons on the display, turns on all relay status LEDs, and turns on the alarm.

Resetting the Maximum Stored Temperature

Press the maximum temperature RESET button to clear the memory of the maximum stored temperature. This causes the current highest winding temperature to become the stored maximum temperature.

Controller Error Codes

During normal operation, the controller is constantly checking itself for proper operation. If a problem is detected, the controller displays one of the error codes described in Table 6.

Table 6: Error Codes

Display	Reason	Description	Corrective Action
– – –	Failed thermocouple or reversed connection	Shows **– – –** on the display when that particular sensor temperature should be displayed. Shows which sensor is malfunctioning. The system activates the alarm, turns ON the fans, and continues to function using the remaining input channels. If the controller detects an open-circuited thermocouple, the alarm sounds and the faulty channel is displayed. A failed thermocouple does not cause a trip. The **– – –** display also indicates a reversed thermocouple connection when the thermocouple is 30 °C below the terminal block temperature.	1. Inspect the thermocouples for possible damage. If damaged, repair or replace. 2. Make sure the thermocouples are wired according to the wiring diagram on page 9.
E11	Failed A/D converter	Shows **E11** on all channels, turns ON the fan relay, and activates the alarm.	1. Disconnect power to the controller. 2. Remove the hinges and disconnect the wiring. 3. Contact your Schneider Electric representative to obtain a Returned Material Authorization, then return the controller to the Schneider Electric Medium Voltage Transformer Facility.
E22	Failed ambient temperature sensor	Shows **E22** on all channels, sets ambient temperature to 30 °C, activates the alarm, turns ON the fans, and continues to operate using a 30 °C ambient temperature.	
E33	Failed EEROM after initial start up	Shows **E33** on all channels, continues to operate, activates the alarm, and turns ON the fan relay.	
	Failed EEROM at power up	Shows **E33** on all channels, turns ON the fan relay, and activates the alarm.	
Blank	Failed display driver	Blank temperature, that is, nothing is shown on the digital display. The controller continues to operate, activates the alarm, and turns ON the fan relay.

Maintenance

Inspect the controller regularly during normal transformer inspection. The frequency of inspection depends on operating conditions. If the controller is installed in a Square D™ brand transformer that is operating in usual service conditions as defined in IEEE C57.12.01, an inspection every five years may be sufficient. However, for unusual locations where the air is contaminated with particles such as dust or chemical fumes, the transformer and controller should be inspected every three months or sooner. After the first few inspections, determine a more definite schedule based on the existing conditions. Perform the following procedures for maintenance.

NOTE: If any problem is found during maintenance, contact your local Schneider Electric representative.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Before performing this procedure, review “Safety Precautions” on page 6.
- Before servicing the controller, turn OFF power to the controller and fans.

Failure to follow these instructions will result in death or serious injury.

Testing the Fans or Blowers

The controller has an automatic fan exerciser that turns the fans ON for a short time at preset intervals. However, during a scheduled inspection of the transformer, turn the blowers or fans ON to confirm that they are working properly. See “Manually Controlling the Fans or Blowers” on page 14.

Testing the Controller

Start the controller’s test sequence by pressing the SILENCE/TEST button while an alarm is not sounding. The temperature display shows the stored set points and the internal temperature of the controller. The controller also tests the digital LCD display, all the LEDs, and the alarm buzzer. For details, see “Reviewing Set Points” on page 15.

Specifications

For reference purposes, typical controller specifications are shown in Tables 7–11.

Thermocouples and the Temperature Display

Three Type K thermocouple sensors are factory-connected to TB4-1(+) and 2(-); TB4-3(+) and 4(-); and TB4-5(+) and 6(-). See Figure 2 on page 9.

NOTE: If replacement of a thermocouple is required, use only Type K thermocouples. Connect the YELLOW lead to a positive terminal (1, 3, or 5) and the RED lead to a negative terminal (2, 4, or 6).

The digital temperature displayed is always the total of ambient plus approximate hot-spot temperatures, not the average temperature rise. For example, a transformer is rated for a 150 °C average temperature rise when carrying the rated full load in a 20 °C ambient temperature. The thermocouple sensors are installed near the theoretical hot spot of the coils. NEMA and IEEE standards permit a 30 °C maximum differential between average and hot-spot temperatures.

Therefore, the digital display would indicate approximately 20 °C + 30 °C + 150 °C = 200 °C total. The alarm would operate at this point to warn that the transformer is approaching the maximum temperature limit of the insulation system.

Hazard Categories and Special Symbols

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates a hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a hazardous situation which, if not avoided, **could result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a hazardous situation which, if not avoided, **could result in** minor or moderate injury.

NOTICE

NOTICE is used to address practices not related to physical injury. The safety alert symbol is not used with this signal word.

NOTE: Provides additional information to clarify or simplify a procedure.

Please Note

Section 1—Introduction

This manual contains instructions for the proper installation, operation, and maintenance of Power-Style™ QED-2 switchboard equipment manufactured by Schneider Electric. Engineering, installation, and operating staff supervisors should familiarize themselves with this manual and become acquainted with the appearance and characteristics of each piece of equipment mounted or contained in the switchboard.

These instructions and procedures apply to Power-Style QED-2 switchboard installations by Schneider Electric. When special features or non-standard components are incorporated in the switchboard, detailed instructions for these components are included in the instruction material holder.

NOTE: There are references to Series 2 switchboards in several places in this instruction bulletin. To determine if the QED-2 switchboard is a Series 2 model, check the rating nameplate located on the front cover. If the switchboard is a Series 2 model, the nameplate indicates that. If it is not a Series 2 model, there is not a Series designation.

Inspection and Packaging

Every Power-Style QED-2 switchboard is carefully inspected and packaged at the assembly plant. Construction of the switchboard is checked, both structurally and electrically, for compliance with all specifications, codes, and standards. After a complete inspection, the switchboard is prepared for shipment. Each section is shipped separately for easier handling before installation. The factory order number, an identification number, and the shipping weights are plainly marked on each shipping section.

Document Replacement

Contact your local Schneider Electric representative to replace lost or damaged wiring diagrams and instruction sheets. Use the factory order number as a reference.

Section 2—Safety Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must be installed and serviced only by qualified personnel.
- Perform such work only after reading and understanding all of the instructions contained in this bulletin.
- Turn off all power supplying this equipment before working on or inside equipment.
- Before performing visual inspections, tests, or maintenance on this equipment, disconnect all sources of electric power. Assume all circuits are live until they are de-energized, tested, and tagged. Pay particular attention to the design of the power system. Consider all sources of power, including the possibility of backfeeding.
- Always use a properly rated voltage sensing device to confirm power is off.
- Practice lock-out/tag-out procedures according to OSHA requirements.
- Handle this equipment carefully and install, operate, and maintain it correctly in order for it to function properly. Neglecting fundamental installation and maintenance requirements may lead to personal injury, as well as damage to equipment or other property.
- Carefully inspect your work area and remove any tools and objects left inside the equipment.
- Replace all devices, doors, and covers before turning on power to this equipment.
- All instructions in this manual assume that the customer has taken these measures before performing maintenance or testing.

Failure to follow these instructions will result in death or serious injury.

Section 3—Receiving, Handling, and Storing

Receiving

Upon receipt, check the packing list against the equipment received to ensure the order and shipment are complete. Also upon receipt, immediately inspect switchboard sections for any damage that occurred in transit. If damage is found or suspected, file a claim with the carrier immediately and notify the nearest Schneider Electric representative.

Handling

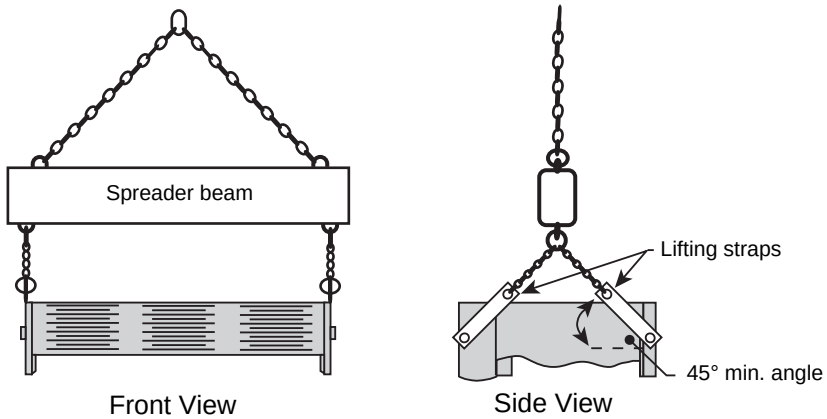
⚠ WARNING

SPECIAL HANDLING REQUIREMENTS

- Do not lay the equipment on its front or sides.
- Lay equipment only on its back when special handling is required.
- Do not ship the equipment lying down.

Failure to follow these instructions can result in serious injury or equipment damage.

Ensure that proper equipment, such as an overhead crane, is available at the installation site to handle the switchboard. This equipment helps avoid injury to personnel and damage to the switchboard.



The shipping weight of each shipping section is marked on the packing list. Verify the lifting capacity of the equipment being used to handle the switchboard in accordance with the shipping weight of each shipping section. Keep the switchboard upright during handling.

Schneider Electric recommends using an overhead crane, lifting straps, and cables or chains to handle the switchboard. This method and alternative handling methods are discussed in this section.

Handling with Lifting Straps

Schneider Electric provides lifting straps as standard equipment for NEMA Type 1 switchboard shipping sections rated 3,000 A or less. Instruction labels on each shipping section include drawings and written instructions outlining the proper use of the lifting straps (Figure 1). Use rigid spreaders or a spanner bar to provide vertical lift on the lifting straps. This helps avoid damage to the frame or finish.

Figure 1 – Lifting with an Overhead Crane, Lifting Straps, and Cables or Chains

© 1988–2015 Schneider Electric All Rights Reserved

ENGLISH

Follow these instructions to handle the switchboard:

1. Use load-rated cables or chains with safety hooks or shackles. Do not pass cables or chains through holes in lifting straps.
2. Use a load-rated spreader beam to prevent structure damage. Rig so that the minimum angle between the lifting cables or chains and equipment top is 45 degrees.

Follow these instructions for laying equipment on its back:

1. Remove shipping skid and equipment back covers.
2. Use overhead cranes, lifting straps, and cables or chains for laying equipment on its back.
3. Rate of drop or pickup for laying equipment on its back is four feet per minute or less.
4. Reverse the procedure to stand the equipment in its upright position.
5. Reinstall back covers.

The warning label (Figure 2) is attached to both the front and rear of the switchboard.

Figure 2 – Warning Label, Rainproof Switchboards

Handling without Lifting Straps

Lifting straps are not furnished on shipping sections rated more than 3,000 A, or on rainproof switchboards. Use rollers, slings, or other means to handle the shipping sections. The handling label (Figure 3) is affixed to each of these sections.

Figure 3 – Handling Instruction Label, Switchboards without Lifting Straps

⚠ WARNING

TOP HEAVY LOAD—HAZARD OF TIPPING

- Stabilize the shipping section to reduce the possibility of tipping.
- Consult with a certified rigging and lifting expert for any situation not covered in these instructions.

Failure to follow these instructions can result in death or serious injury.

When elevating a shipping section not equipped with lifting straps, use an overhead crane equipped with either of the following:

- A chain coupled to a sling rigging
- A wire cable with safety hooks and shackles

Wrap the sling completely around the switchboard and shipping stringers.

NOTE: A forklift is an alternative method of handling the switchboard. Always check the fork lengths to ensure that the forks extend under the entire switchboard. Carefully balance the load, and always use a safety strap when handling or moving a switchboard with a forklift (Figure 4 on page 15).

Storing

When storing the switchboard before installation, cover the top and openings of the equipment during the construction period to protect the switchboard from dust and debris.

If a switchboard is not installed and energized immediately, store it in a clean, dry space with a consistent temperature to prevent condensation. Store the switchboard indoors, if possible. Preferably, store it in a heated building with adequate air circulation and protect it from dirt, fumes, water, and physical damage. Storing the switchboard outdoors can cause harmful condensation inside the switchboard.

NOTE: Install portable electric heaters of approximately 250 watts per vertical section in both indoor-type and rainproof-type switchboard enclosures for adequate protection during storage.

Before energizing the space heaters, remove all loose packing or flammable materials inside the switchboard. Outdoor switchboards are not weather-resistant until completely and properly installed; treat them the same as indoor switchboards until after installation.

Special Handling Requirements

Do not lay the equipment on its front or sides. Doing so will damage unit.
Lay equipment only on its back when special handling is required.
See Instruction Bulletin for special handling instructions for laying equipment on its back.
Equipment is NOT to be shipped lying down.
Failure to follow these instructions can result in death, serious injury or equipment damage.

Requisitos especiales de manejo

No coloque el equipo sobre su frente o lados ya que podría dañarse la unidad.
Coloque el equipo sobre su parte posterior solamente cuando sea necesario manejarlo de manera especial.
Consulte el boletín para obtener las instrucciones especiales de manejo para colocar el equipo sobre su parte posterior.
El equipo NO deberá transportarse acostado.
El incumplimiento de estas instrucciónes puede causar la muerte, lesiones serias o daño al equipo.

Exigences de manutention spéciales

Ne couchez pas l'appareil sur sa face avant ou sur las côtés. Faire ainsi l'endommagerait.
Couchez l'appareil sur le dos uniquement lorsqu'une manutention spéciale est nécessaire.

Section 4—Installation

Correct installation of Power-Style QED-2 switchboards is essential for proper operation of all switchboard components. Study the associated instruction books and all drawings carefully. In most cases, all drawings are sent to the purchaser before a switchboard is shipped to enable adequate planning.

NOTE: The top of the switchboard will not support the weight of the installer.

Location

Find the designated area on the building floor plan where the switchboard will be installed. The location chosen for installation should provide working clearances complying with Section 110-26 of the National Electrical Code® (NEC®) or Section 2-308 of the Canadian Electrical Code (CEC) Part 1.

- Front-accessible switchboards require field connections, including mains, branches, ground bus, and neutral bus, to be accessible and maintainable from the front.
- For switchboards having rear ventilation, allow a minimum 1/2-in. (13 mm) clearance between the rear of the switchboard and the wall for proper ventilation. Equipment drawings identify switchboards requiring rear or side access.
- Switchboards that require rear access for installation, field connections, or maintenance (such as filter replacement), require 30 in. (762 mm) of working space per NEC 110-26.
- If the switchboard is in a wet location or outside of the building, enclose it in an outdoor enclosure or equipment to prevent moisture or water from entering and accumulating within the enclosure. Outdoor-rated switchboards drain to the rear, so there must be at least a 1/2-in. (13 mm) clearance between the rear of the switchboard and a wall or other obstruction for proper drainage.

Foundation Preparation

The floor or foundation must be strong enough to support the weight of the switchboard without sagging. The surrounding floor area should gently slope toward a drain.

NOTE: For seismic qualifications, read the section “Anchoring for Seismic Qualifications” on page 20 before pouring the floor or foundation.

Power-Style QED-2 switchboards are assembled on true and level floors at the assembly plant. To ensure correct bus bar alignment, the mounting pad or final installation site must be smooth and level. If parallel steel floor channels are imbedded for mounting the switchboard, take extra care to ensure the floor channels are level over their entire length to avoid distortion of the switchboard structure. Each channel should be level with the finished floor.

When pouring the foundation, make provisions for conduits entering the switchboard from below and carrying the incoming and/or outgoing cables, control wiring, and ground cable. The bottom view in the equipment drawing shows the available conduit area for correct layout.

Conduits should project above the finished floor by about 2 in. (51 mm). However, to simplify moving the shipping sections into place, install the conduits flush with the concrete and, after the sections are in their final position, add the appropriate extension sleeves. Otherwise, raising the shipping section on timbers or lifting it by a crane to

© 1988–2015 Schneider Electric All Rights Reserved

clear the conduit hubs will be necessary. Before pouring the foundation, consider installing additional conduits for future circuits.

Switchboard Preparation

Remove dirt and debris from the foundation and surrounding area before moving the switchboard into final position.

After the switchboard has been moved to its final installation site, take each shipping section off its shipping stringers. For switchboards greater than 24 in. (610 mm) deep, the center base channel can be removed.

Remove all packing materials. If the switchboard is equipped with a bottom closure plate in each vertical section, remove and retain the plates for reuse. When bottom closure plates are furnished, the customer must make any holes necessary for conduit entering the bottom of the switchboard. After making the holes, reinstall the closure plate.

General Installation

NOTICE

HAZARD OF EQUIPMENT DAMAGE

Level and align adjacent shipping sections with one another. Ensure proper alignment of horizontal main through bus and proper splice bus connections.

Failure to follow these instructions can result in equipment damage.

Install the switchboard into its final position by leveling progressively each section and bolting the frames together, if separated. Position shipping sections as follows:

1. Maneuver each shipping section into the desired position using the procedures under “Handling” on page 11.
2. Carefully lower the section over the conduit stubs to comply with the “available conduit area” as shown in the bottom view of the equipment drawings. Otherwise, there might not be sufficient cable bending space.
3. Level the shipping section.
4. After installation of each section is complete, make the through bus splice connection to the preceding section before installing the next section.

Joining Shipping Sections—Outdoor Switchboards

1. Remove the center top cap (Figure 5) from the left-hand section, and retain all hardware for reuse.

Figure 5 – Joining Adjacent Sections—Outdoor Switchboards

Detail A **Detail B**

2. When possible, open or remove the front and rear doors and panels, providing access to bolt adjacent shipping sections together.
3. Remove three 0.5-in. (13 mm) diameter knockouts from the front vertical corner channel and three from the rear vertical corner channel (a total of six per frame side) as indicated by the arrows in Figure 5.
4. Position each adjacent section, carefully leveling it and aligning it with the previous section. If lifting straps are provided, completely remove them from

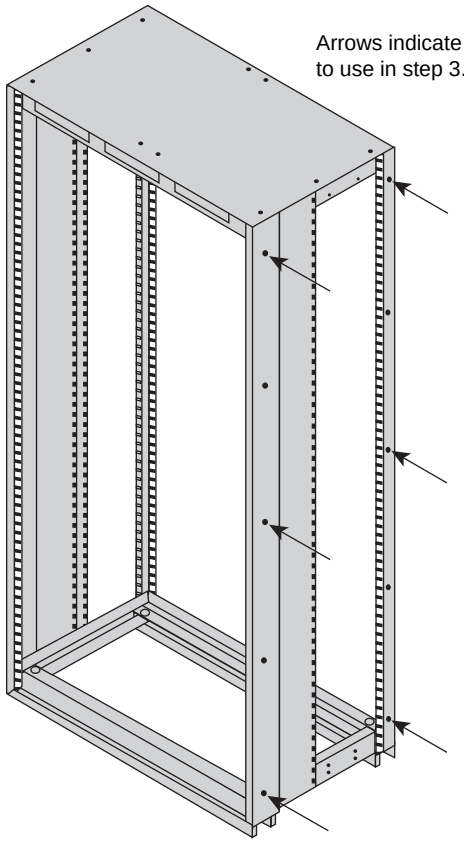
the sides being bolted together so the sections can be joined flush. The only gasket required between sections is provided on the roof flange.

NOTE: If lifting strap removal is not required to join sections, leave the lifting strap on the switchboard. Verify that the bolt is tight to maintain NEMA Type 3R integrity.



5. Six bolts (3/8-16 x 1 in.) are provided. Place them through the holes created in step 3 to join adjacent sections.
6. Make the through bus splice connections to the preceding section.
7. Replace the center top cap removed in step 1.
8. Replace and secure the front and rear doors and panels removed in step 2.

Joining Shipping Sections—Indoor Switchboards

1. Position each adjacent section, carefully leveling and aligning it with the previous section. If lifting straps are provided, completely remove them from the sides being bolted together so the sections can be joined flush.

   NOTE: Leave the other lifting straps on the switchboard if their removal is not required to join adjacent sections flush.

2. Open or remove the front and rear doors and panels, providing access to bolt adjacent shipping sections together.
3. Six bolts (3/8-16 x 1 in.) are provided. Place the bolts through the existing holes in the front and rear vertical corner channels to join adjacent sections (Figure 6).
4. Make the through bus splice connections to the preceding section.
5. Replace and secure all front and rear doors and panels removed in step 2.

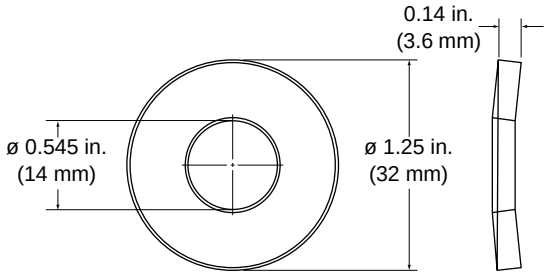
Anchoring for Seismic Qualifications

QED-2 equipment that is seismically certified has been qualified to the site-specific seismic requirements of the listed model building codes and/or standards. Optional construction features may be required, depending on the location of the installation and the particular code and/or standard of interest. Seismic certificates of compliance are provided with all seismically certified QED-2 equipment. To maintain the validity of this certification, the installation instructions provided in this bulletin must be followed.

Responsibility for Mitigation of Seismic Damage

For the purposes of the model building codes, QED-2 equipment are considered nonstructural building components. Equipment capacity was determined from triaxial seismic shake table test results as defined in the International Code Counsel Evaluation Service (ICCES) Acceptance Criteria for Seismic Qualification Testing of Nonstructural Components (AC156). Unless otherwise indicated, an equipment importance factor of 1.5 (Ip = 1.5) was used, indicating that equipment functionality was verified before and after shaker table seismic simulation testing. This importance factor is indicative of critical facilities where maximizing the probability of post event functionality is a priority. The Building Seismic Safety Council (BSSC) recognizes AC 156 as an appropriate methodology in the 2003 National Earthquake Hazard Reduction Program (NEHRP) Commentary (FEMA 450 Part 2). The National Institute of Building Sciences established the BSSC in 1979 to develop and promote regulatory provisions for earthquake risk mitigation at the national level.

Incoming and outgoing cable and conduit must also be considered as related but independent systems. They must be designed and restrained to withstand the forces generated by the seismic event without increasing the load transferred to the equipment. For applications where seismic hazard exists, bottom entry and/or exit of cable and conduit is preferred. This system must be able to transfer the loads created by a seismic event to the load-bearing path of the building structural system.



Maintaining Seismic Certification

Seismic qualification of nonstructural components by Schneider Electric is just one link in the total chain of responsibility required to maximize the probability that the equipment will be intact and functional after a seismic event. During a seismic event, the equipment must be able to transfer the loads that are created through the mounting pad and anchorage to the load-bearing path of the building structural system. The structural civil engineer or design engineer of record is responsible for detailing the equipment connection and anchorage requirements for the given installation. The installer and manufacturers of the anchorage restraint system are responsible for assuring that the mounting requirements are met. Schneider Electric is not responsible for the specification and performance of these systems.

Anchoring QED-2 Equipment for Seismic Applications

Figure 7 – Belleville Washer

Formed base channels run the width of the section. The channels and connecting braces provide a minimum 0.75-in. (19 mm) diameter hole for fastening the section to the floor. To anchor the QED-2 switchboard to the floor properly, use all four mounting locations for NEMA Type 1 enclosures less than 36 in. deep, all six mounting locations for 36–70 in. deep enclosures, and six of the eight mounting locations for enclosures greater than 70-in. deep (see Figure 8 on page 23).

Use 0.5 in. (13 mm) diameter anchor bolts (Grade 5 minimum, provided by others) for the installation of equipment. Use one 1.25 in. (32 mm) outer diameter Grade 5 Belleville washer (provided by others; see Figure 7) under the head of each bolt or anchor nut. To develop the full strength of the anchor, torque the hardware to the value specified by the anchor manufacturer, or as recommended in the seismic restraint detailing supplied by the Structural Civil Engineer of record for the project (see Figure 9 on page 24).

Additionally, each NEMA Type 1 enclosed section includes four top-located hard points for attaching two upper lateral braces (braces and hardware supplied by others) to the QED-2 structure for top structural restraint (see Figures 10 and 11 on page 25).

Top structural restraint is required for all QED-2 equipment installed:

- where the site-specific 0.2 second spectral ground motion exceeds 2.67 g (as determined from the code-referenced ground motion maps or the site-specific seismic hazard engineering study), or
- when displacement at the top of the equipment cannot be tolerated, or
- for all QED-2 corner sections used for seismic applications.

To develop the full strength of the upper structural anchor, install and torque the hardware as specified by the anchor manufacturer or the seismic restraint detailing supplied by the Structural Civil Engineer of record for the project.

NOTE: Anchoring hardware is not furnished with the QED-2 equipment.

After the QED-2 switchboard and adjacent equipment are properly joined and the entire structure is bolted to the floor, install the incoming service conductors and load side cables. During an earthquake, the top of the QED-2 switchboard can move in any direction. Any top incoming cables must accommodate this motion. Do not use the QED-2 enclosure (particularly the top) to mount exterior equipment.

2. Depending on the frame size (see Figure 8 on page 23), use either four or six 1/2-13 Grade 5 bolts in the locations shown in Figure 9.

Figure 9 – Base Channel Mounting Hardware

NOTE: Base channel mounting hardware detail shown for reference purposes only. Anchoring hardware is not furnished with the switchboard. Covers and internal hardware shown removed for illustration purposes.

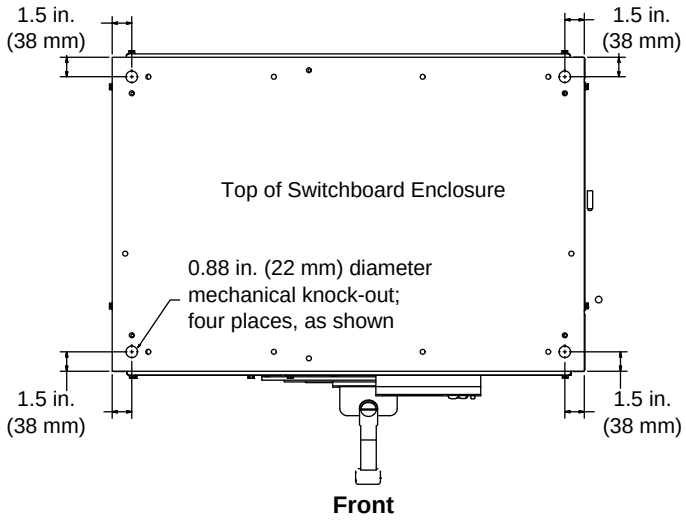
3. Once the switchboard is in place, secure the base channels to each bolt using a 1.25 in. (32 mm) diameter Belleville washer between a 1/2-13 hardened nut and the switchboard frame as illustrated in Figure 9.

   NOTE: The “TOP” side of the Belleville washer must be facing the nut.

4. Torque each nut to the value recommended by the anchor manufacturer to develop the full strength of the anchor.

Top Anchoring/Restraint

For installation at locations with an Ss greater than 2.67 g (as determined from the current version of the International Building Code), or where displacement cannot be tolerated at the top of the switchboard during a seismic event, use top restraints attached to the equipment hard points.



NOTE: Anchoring hardware is not furnished with the switchboard.

1. The four 0.88-in. (22 mm) diameter mechanical knock-outs shown in Figure 10 on page 25 serve as hard points for application of a top restraint system.

   NOTE: By code, it is the responsibility of the Building Design Professional to determine the top restraint methodology for the intended building application.

2. Detach the top plate from the main switchboard enclosure. Retain the screws.
3. Remove the four 0.88 in. (22 mm) diameter mechanical knock-outs as directed by the Building Design Professional.
4. With the knock-outs removed, reattach and re-secure the top plate to the enclosure using the screws removed in Step 2.
5. Attach the top restraint system using a 1/2-13, Grade 5 bolt, a 1 in. (25 mm) diameter steel washer, a 1.25 in. (32 mm) diameter Belleville washer, and a hardened 1/2-13 nut as shown in Figure 11.

Anchoring the Switchboard

Although sections are freestanding, a hard bump or shifting movement can result in damage to the splice joints between sections and conduit hubs connected to the sections. Therefore, each vertical section must be anchored to the floor.

Formed base channels run the width of the shipping section. The channels have 1.12-in. (28 mm) diameter holes for fastening the section to the floor (Figure 12). Anchor each section to the floor with 1/2-in. (Grade 2 minimum) bolts with flat washers and anchors suitable for installation of electrical equipment (not furnished).

Figure 12 – Switchboard Base Channels

After all switchboard sections are properly joined and the entire structure is bolted to the floor, install the incoming service conductors and load side cables.

NOTE: If the switchboard consists of only one shipping section, proceed to “Grounding and Bonding” on page 28.

Through Bus Splice Connections

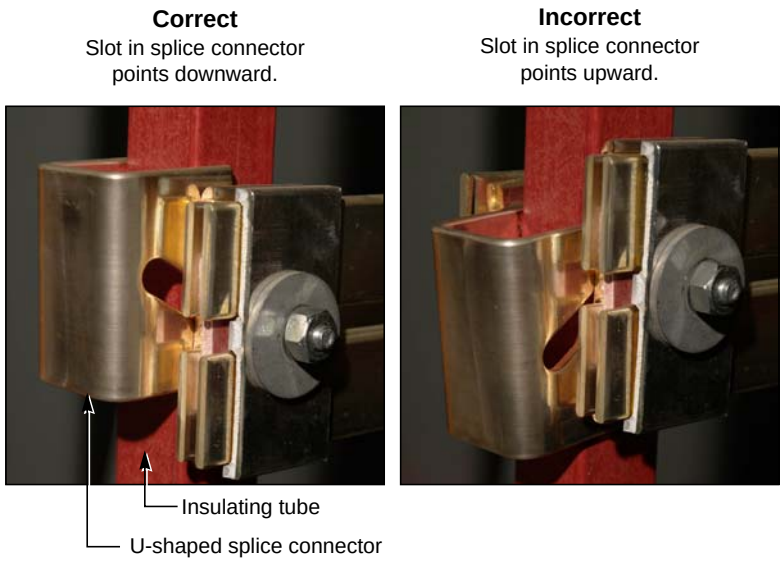
⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Do not install through bus splice connectors with the switchboard energized.

Failure to follow these instructions will result in death or serious injury.

Through bus splice connectors and/or hardware, along with installation instructions, are provided with each shipping split. Follow the installation instructions, and torque splice bolts to the value given in “Section 9—Torque Values for Electrical Connections” on page 53.



If through bus bars are wrapped with an insulative material, cover the splice connections with the material provided.

For splice connections with bus on the front and rear of an insulating tube, ensure the U-shaped, copper connector is centered around the tube. Figure 13 on page 27 shows the proper orientation of the connector.

© 1988–2015 Schneider Electric All Rights Reserved

NOTE: The U-shaped connector will fit snugly against the insulating tube when installed correctly. It is pulled away from the insulating tube in Figure 13 to show the orientation of the connector slot.

Figure 13 – Proper Orientation of U-shaped Splice Connector

Ground Bus Splice Connections

Align and secure the ground bus splice connection between shipping sections. Torque connections to 100 lb-in (11 N•m) (Figure 14 or 15).

NOTE: Proper installation is essential for equipment ground-fault systems.

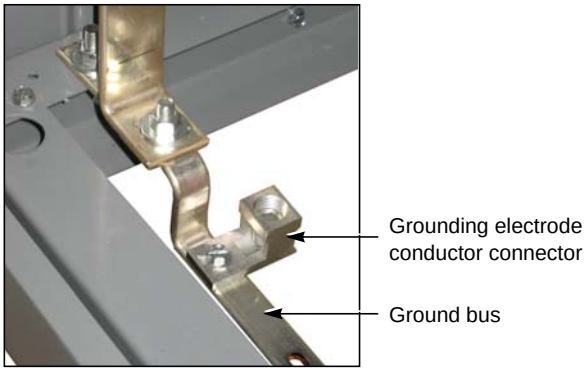
Grounding and Bonding



NOTE: A system is “grounded” if it is grounded at any point ahead of the switchboard, whether the grounded conductor (neutral) is carried through to the loads, or not.

Service Equipment—Grounded System

For solidly *grounded* systems used as either service equipment or as a main switchboard on a separately derived system:

1. Run a grounding electrode conductor from the grounding electrode at the installation site to the grounding electrode conductor connector (ground lug) located on the switchboard ground bus (or on the neutral bus, if so indicated on the equipment drawing) (Figure 16). Select the material and size of this grounding electrode conductor to comply with Sections 250-62 and 250-66 of the NEC or Sections 10-204 and 10-206 of the 1998 CEC, and install it as specified in Section 250-64 of the NEC or Section 10-908 of the 1998 CEC.

Figure 16 – Grounding Electrode Connector

2. Install the main bonding jumper between the neutral bus and the ground bus (Figure 17 or 18 on 29). For torque values, refer to “Section 9—Torque Values for Electrical Connections” on page 53.

   NOTE: If the switchboard is fed from multiple sources (for example, double-ended systems), there may be two or more main bonding jumpers to install.

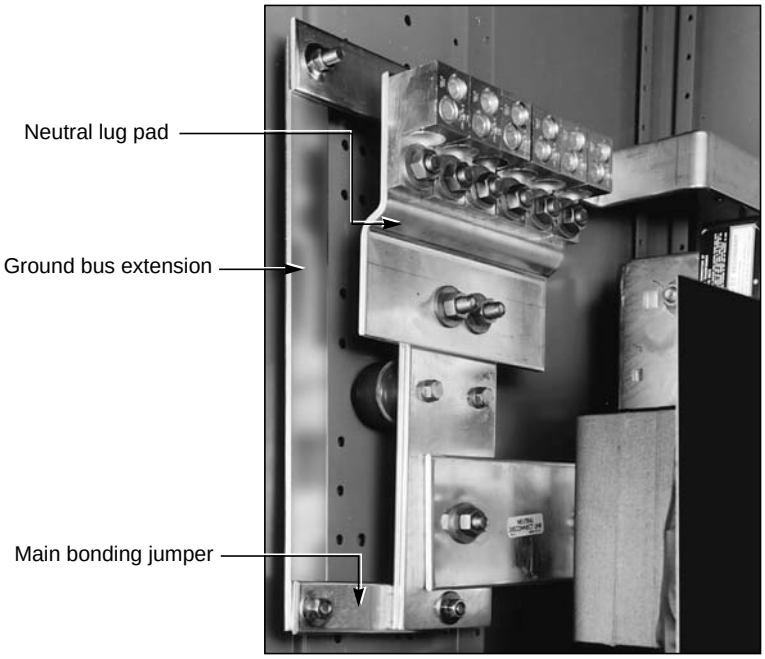
ENGLISH

Figure 17 – Main Bonding Jumper



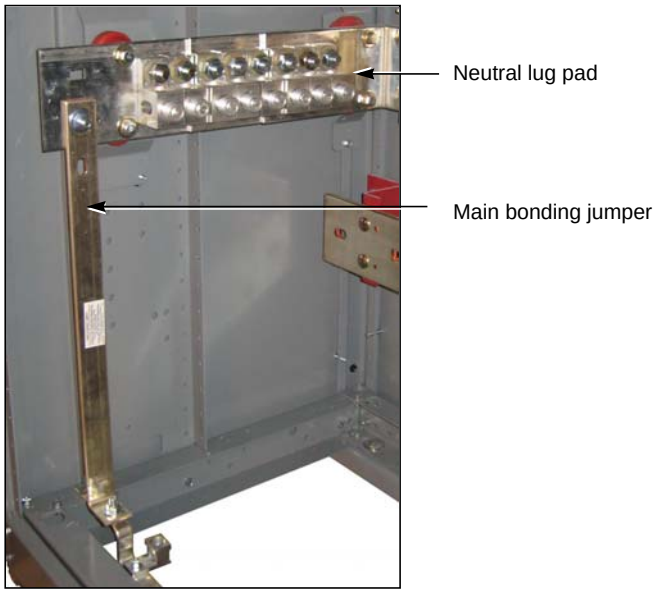


Figure 18 – Series 2 Main Bonding Jumper

In Canada, a main bonding jumper bus or cable is provided between the neutral bus and ground bus. When the bonding jumper must be disconnected (for example, for a Megger® test), remove the main bonding jumper bus or cable lug with cable from the neutral bus. This is normally located near the line neutral lugs. Secure the main bonding jumper bus or cable and lug to maintain the required distance from phases and neutral.

NOTE: If the switchboard is fed from multiple sources (for example, a double-ended system like a main-tie-main), there may be two or more main bonding jumpers installed.

© 1988–2015 Schneider Electric All Rights Reserved

Service Equipment—Ungrounded System

For *ungrounded* systems used as either service equipment, or as a main switchboard on a separately derived system:

1. Run a grounding electrode conductor from the grounding electrode at the installation site to the grounding electrode conductor connector (ground lug) located on the switchboard ground bus (Figure 16 on page 28).
2. Select the material and size of this grounding electrode conductor to comply with Sections 250-62 and 250-66 of the NEC or Sections 10-700 and 10-702 of the 1998 CEC, and install it as specified in Section 250-64 of the NEC or Section 10-204 of the 1998 CEC.

Not Service Equipment

For either *grounded or ungrounded* systems, when a switchboard is not used as service equipment nor as a main switchboard on a separately derived system:

Use equipment grounding conductors sized according to Section 250-122 of the NEC or Section 10-206 of the 1998 CEC to connect the switchboard frame and ground bus to the service ground.

High-Impedance Grounded Neutral Systems

For high-impedance grounded neutral systems:

Ground the system following the instructions provided with the system grounding equipment and in compliance with Section 250-36 of the NEC. Confirm that the switchboard frame and ground bus are bonded in accordance with Section 250-102 of the NEC.

Busway Connections

Schneider Electric switchboards are manufactured with two different styles of busway connections. Qwik Flange™ is used on indoor switchboards only.

The other type of busway connection is the “dummy” flanged end. This type is used on some indoor switchboards, but primarily on outdoor units. The dummy flanged end must be removed to allow actual busway flanged end installation. Either the dummy or actual busway flanged end must be in place before energizing the switchboard.

NOTE: Do not use the switchboard to support the weight of the busway connection. Support busway independently. When busway is installed, make sure no areas of the roof are bowed downward. This will help prevent pooling of water.

Busway Connection—NEMA Type 1 (Indoor) Only (Qwik Flange™)

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Turn off all power supplying the switchboard and busway before installing connections.

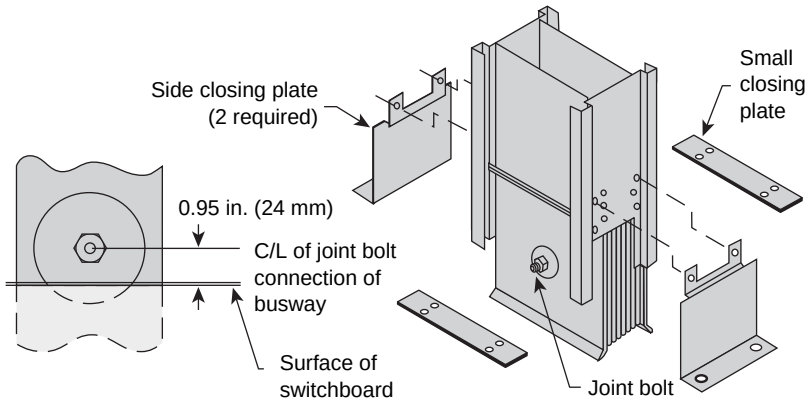
Failure to follow these instructions will result in death or serious injury

Follow the instructions in this section to make Qwik Flange busway connections (see Figures 19 and 20 on page 31):

1. Remove any protective covering from the opening in the switchboard.
2. Slip the busway joint into the switchboard connectors.
3. Check the joint bolt alignment; the center line (C/L) of the joint bolt to the switchboard surface should be 0.95 in. (24 mm) (Figure 19 on page 31).
4. Attach the side closing plates using two 5/16-in. bolts (provided). When installed properly, the holes in the side closing plates align with the holes in both the switchboard and busway.

 © 1988–2015 Schneider Electric All Rights Reserved

Figure 19 – Qwik Flange Installation



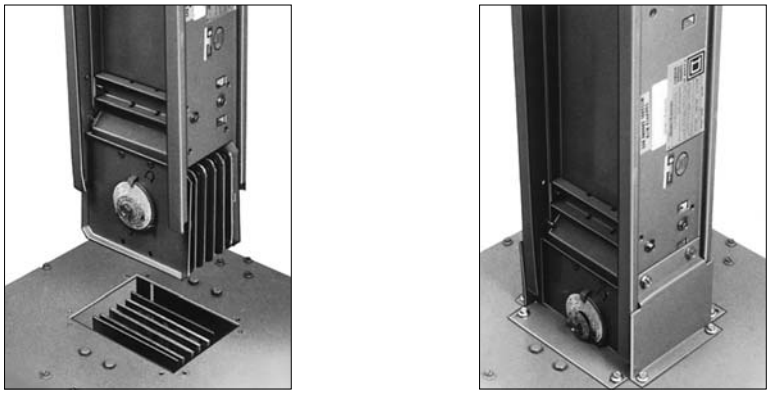


Figure 20 – Qwik Flange

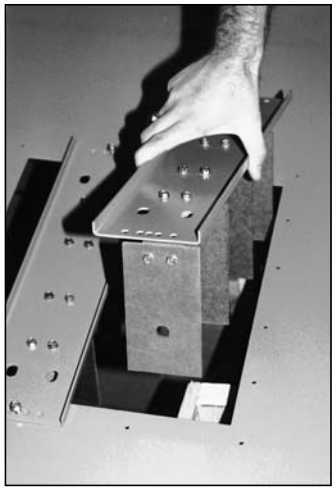
5. Use an 18-in. (457 mm) or longer wrench to torque the joint bolt until the outer break-away head twists off. Do not allow the break-away bolt head or red warning disc to drop into the switchboard.
6. Slip the remaining two small closing plates into position by aligning with the holes in the switchboard. Use the four 1/4-20 screws provided to secure the equipment.
7. Confirm proper phasing of the installed busway before energizing.

 © 1988–2015 Schneider Electric All Rights Reserved

Busway Connections—NEMA Type 1 (Non-Qwik Flange) and NEMA Type 3R

If this style of connection for busway is furnished, the busway "dummy" flanged end must be removed before installing busway (Figure 21 on page 32).

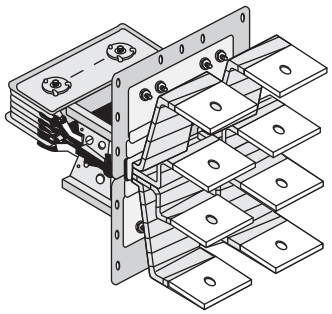
⚠ DANGER



HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Turn off all power supplying the switchboard and busway before installing connections.

Failure to follow these instructions will result in death or serious injury.



1. From inside the switchboard, remove the 1/2-in. bolts that fasten the switchboard bus to the busway dummy nonmetallic flanges. Retain all hardware for reuse.
2. Remove all screws securing the busway dummy flanged end to the switchboard enclosure.
3. Remove the busway dummy flanged end (Figure 21).

Figure 21 – Removing the Busway Dummy Flanged End

4. Install the actual busway flanged end to the switchboard bus connectors provided in the switchboard (Figure 22). Insert the flanges between the switchboard bus connectors so that the mounting holes in the collar of the flanged end align with the pre-drilled holes in the switchboard enclosure.

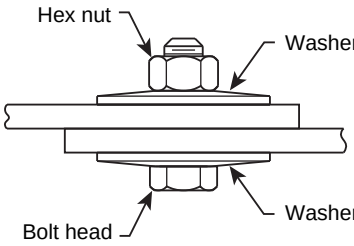


Figure 22 – Flanged-End Connections

 © 1988–2015 Schneider Electric All Rights Reserved

5. Line up the holes in the bus bar flanges, and reinstall the 1/2-in. (13 mm) hardware that was removed in step 1 on page 32 and as shown in Figure 23.

Figure 23 – Reinstalling the 1/2-In. (13 mm) Hardware

NOTE: The convex side (marked “Top”) of one conical washer should be against the bolt head, and the convex side of the second conical washer should be against the hex nut.

6. Torque the bolts inserted in step 5 as indicated in “Section 9—Torque Values for Electrical Connections” on page 53.
7. Assemble the busway collar to the switchboard enclosure with the screws provided.
8. Ensure that the busway integral ground is connected to the switchboard ground bus.
9. Confirm busway phasing before energizing.

Conduit Area

1. Locate and terminate all conduit in the switchboard enclosure in the “available conduit area” designated on the equipment drawing.

   NOTE: On switchboards greater than 24 in. (610 mm) deep, the center base channel can be removed for additional conduit area. **Exception:** Do not remove any base channels when seismic restraint is required.
2. Install the conduit properly. Use hubs, locknuts, and bushings to protect the cables and prevent condensation on the conduit from entering the switchboard.

   NOTE: If top entry, do not use the top of the switchboard to support the weight of the conduit. Support the conduit independently. When conduit is installed, make sure no areas of the roof are bowed downward. This will help prevent pooling of water.

   If bottom closure plates are furnished, the customer must remove the plates, make holes in them for any conduit entering the bottom of the switchboard, and then reinstall the plates.

   Under seismic conditions, consider using top restraints if movement of the top of the switchboard is an issue.
3. Bond all conduit hubs to the switchboard enclosure with approved electrical connections.

Cable Pulling

Power-Style QED-2 switchboards are constructed to customer specifications for the cable entrance arrangement (for example, top or bottom feed). Switchboard components are arranged to give proper cable clearance and bending space for cables entering or exiting the switchboard as specified on the equipment drawing.

1. Use only cable sizes suitable for a proper fit with the corresponding lugs.
2. Pull the proper number of line side and load side cables according to the load served and the NEC or CEC.
3. Position the cables inside the switchboard so that they are not subject to physical damage.
4. Maintain the largest possible bending radii and proper clearance to bus bars and grounded parts. If any cables are lying or bearing on structural members, support them to relieve this condition or place suitable protective material at the bearing point to protect the cable insulation.
5. Be certain to run all phase conductors, including the neutral, through the same opening where cables enter or leave the switchboard, or pass through any metal that has magnetic properties. Otherwise, overheating can result. See Section 300-20(a) of NEC.
6. When instructed, brace or cable-lace the conductors.

Cable Terminations

1. Use a proper insulation stripping tool to strip a length of insulation from the end of the cable sufficient to fit into the full length of the lug barrel. Be careful not to nick or ring the strands.
2. Thoroughly clean aluminum cable contact surfaces with a wire brush, or scrub them with an abrasive cloth to remove oxides and foreign matter.
3. Immediately apply an acceptable joint compound to the bare aluminum surfaces.
4. If compression-type lugs are furnished on any switch or circuit breaker, or as the main incoming power lugs, unbolt and remove them to create sufficient room for crimping the lugs to the cables with the crimping tool.
   a. Insert the cable into the lug barrel and, using the crimping tool, make the specified number of crimps per the recommendations of the manufacturer.
   b. Wipe excess joint compound from the connector and insulation.
   c. With the cables connected, remount the lugs onto the bus bars, switches, or circuit breakers. Torque the bolts to the values given in “Section 9—Torque Values for Electrical Connections” on page 53.
5. Set screw-type lugs may be furnished as main incoming lugs and are standard on molded case circuit breakers and QMB/QMJ/QMQB[1] fusible switches. Torque these lugs to, **but do not exceed**, the specified values. Torque values for circuit breaker and switch lugs are marked on these units. Torque values for other switchboard lugs are marked on the switchboard (Table 7 on page 53).

[1] QMQB switches are available in Canada only.

Cable Restraint for Short-Circuit Current Rating (SCCR)

Cable restraint is recommended for lugs mounted on bus when the following conditions are met:

- Unsupported cable lengths are greater than 3.5 ft. (1 m) [1]

AND

- Cables meet the **Yes** criteria shown in Table 2.

Table 2 – Cable Restraint Criteria

Cable Ampacity	Available Short Circuit Fault Current (RMS)			
	< 65 kA	65 to < 85 kA	85 to < 150 kA	150 to 200 kA
≤ 800 A	No	Yes	Yes	Yes
1200 A	No	No	Yes	Yes

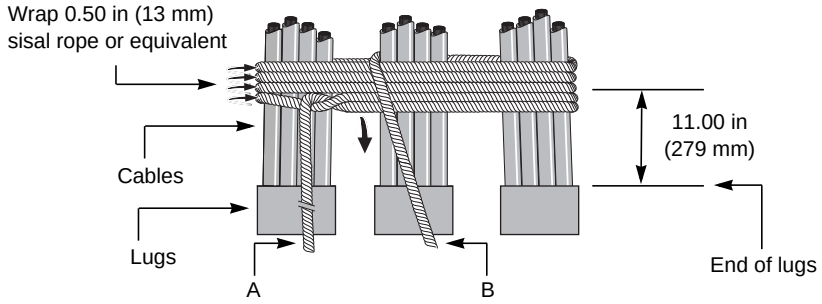
NOTICE

HAZARD OF CABLE MOVEMENT UNDER SHORT-CIRCUIT CONDITIONS

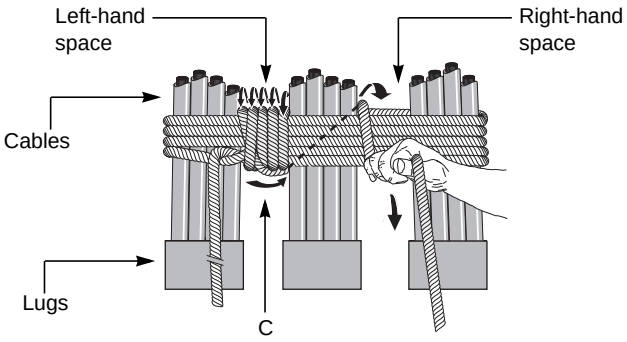
Restrain all cables, including neutral cables, in the switchboard installation when the conditions stated on page 35 are met.



Failure to follow these instructions can result in equipment damage.

When cable restraints are required, perform the following steps.

NOTE: Wrap cables using 1/2-in. (13 mm) diameter sisal rope, 3/8-in. (9.5 mm) diameter nylon rope, or equivalent.



1. Begin wrapping the cables (Figure 25) a maximum distance of 11 in. (279 mm) from the end of the lugs. Continue to wrap the cables on 11-in. (279 mm) center(s) up to the point where the cables leave the enclosure.
   a. Wrap the cables four (4) times as shown, leaving 3 ft. (1 m) of excess rope at the first end (A).
   b. Pull the rope (B) taut.

Figure 25 – Wrapping Cables (neutral cables not shown)

2. Wrap the rope several times (Figure 26) until the space between the cables is completely filled.
   a. Weave the final rope loop underneath the previous loop (C).
   b. Bring the rope through the right-hand space.
   c. Pull the rope taut.

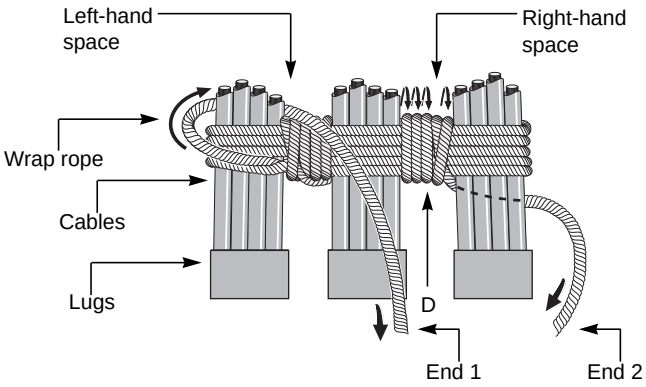


Figure 26 – Wrapping the Space Between Cables

3. Wrap the rope several times until the space between the cables (Figure 27) is completely filled.
   a. Weave the final rope loop underneath the previous rope loop (D).
   b. Pull the rope taut.

Figure 27 – Finish Wrapping the Space Between Cables

4. Tie the rope ends (1) and (2) together (Figure 28) until they are taut. Cut off excess rope, and tape ends to prevent fraying.

Figure 28 – Tying Rope Ends Together

5. Recheck torques of wire binding screws after securing the cables.

   NOTE: Refer to the torque label supplied with the switchboard for torque values.

Section 5—Pre-energizing Checkout Procedure

Conduct a complete inspection **before** the switchboard is energized to ensure that all components function and operate properly. **Complete every step of the checkout procedure listed before energizing the switchboard.**

1. Check all field-installed bus bar connections. Torque values are listed in “Section 9—Torque Values for Electrical Connections” on page 53.
2. Check all accessible connections for tightness.
3. Check all factory- and field-installed lug terminations for tightness.
4. Check the rigidity of all bus bar supports.
5. Check the switchboard enclosure for dents or other damage that reduces electrical clearances inside the switchboard.
6. Remove all foam blocks, or other temporary cushioning or retaining material, from the electrical devices.
7. Manually open and close all switches, circuit breakers, and other operating mechanisms, checking for correct alignment and free operation.
8. Operate all electrically operated switches, circuit breakers, and other devices equipped with remote operators (not under load). An auxiliary source of control power may be necessary to accomplish this.
9. Check all relays, meters, and instrumentation to verify that all field- installed wiring connections are made properly and that the devices function properly.
10. Current transformers (CTs) supplied for customer use require connection to a metering device load before energizing. Verify that the metering device load is properly connected, including main switchboard connections to remote equipment.
11. All CT circuits supplied by Schneider Electric for customer metering use are shorted for shipment. Remove shorting terminal screws on shorting terminal blocks or jumpers and store in the block.
12. Factory-installed circuit breakers may have an adjustable magnetic or electronic trip which is factory set to the lowest setting. To provide coordinated operation during a fault, adjust the trip as outlined in the instruction manual provided with the circuit breaker. All poles are adjusted simultaneously, using a screwdriver, by the single setting.
13. If ground-fault protection is furnished on type BP switch, adjust the relay to the desired ground current pickup setting. The relay is shipped from the factory at the lowest setting of 120 A for the relay. Relay pickup range is from 120–1,200 A for the relay.

    NOTE: For molded case circuit breakers, refer to “Section 11—Reference Publications” on page 56 for circuit breaker information.
14. Check the torque on all bolts of the fuses mounted in Bolt-Loc™ switches, 21–30 lb-ft (28–41 N•m), and in QMB/QMJ/QMQB[1] switches (as marked on the device).

[1] QMQB switches are available in Canada only.

NOTICE

HAZARD OF EQUIPMENT DAMAGE

Do not pry open or spread the fuse mounting clips. Doing so can cause a loose connection, resulting in overheating.

Failure to follow these instructions can result in equipment damage.

15. Examine fuse clip contact pressure and contact means (QMB/QMJ/QMQB[1] fusible switches). If there is any sign of looseness, contact Schneider Electric Services at 1-888-778-2733 (US) or 1-800-565-6699 (Canada). Loose fuse clips can result in overheating.
16. Check all QMB/QMJ/QMQB[1] fusible switches, verifying that the proper fuses with the required interrupting rating and continuous current rating are installed. Do not use renewable link fuses in Square D™ brand fusible switches.
17. Verify that all grounding connections are correctly made. If the switchboard is used as a service entrance, double check to see that the main bonding jumper is connected (Figure 17 on page 29).

⚠CAUTION

HAZARD OF EQUIPMENT DAMAGE OR INJURY

- Remove the long-time rating plug before electrical insulation testing a circuit breaker that has a label stating “Warning: Disconnect Plug Before Dielectric Test.”
- Some Micrologic™ trip units are not rated for voltages that would occur during electrical resistance insulation testing.
- Open all control and metering disconnects from the control circuits.

Failure to follow these instructions can result in injury or equipment damage.

18. Conduct an electrical insulation resistance (Megger®) test to ensure that the switchboard is free from short circuits and undesirable grounds.
    a. Open all control power and metering disconnects or remove the fuses from the control circuits.
    b. Disconnect the neutral connection at any surge protective device or other electronic device before performing the electrical insulation resistance test; reconnect to the device after the test.
    c. With the neutral isolated from the ground and the power switches and circuit breakers open, conduct electrical insulation tests from phase-to-phase, phase-to-ground, phase-to-neutral, and neutral-to-ground.
    d. If the resistance reads less than one megohm while testing with the branch circuit devices in the open position, the system may be unsafe and should be investigated.
    e. Consult Schneider Electric Services at 1-888-778-2733 (US) or 1-800-565-6699 (Canada) to help correct any problems.
19. After completing the electrical insulation resistance test, replace all control power fuses that were removed and close power disconnects that were opened.
20. Check all field-installed wiring. Make certain it is clear of all live parts, and when instructed, secured to withstand fault currents.

 © 1988–2015 Schneider Electric All Rights Reserved

21. Verify that all control wiring between sections is connected.
22. Vacuum to remove any dust, scrap wire, or other debris.

NOTICE
HAZARD OF EQUIPMENT DAMAGE Do not use an air hose to blow out the switchboard. Dust can settle inside relays and overcurrent devices, causing overheating and improper operation. **Failure to follow these instructions can result in equipment damage.**

23. Replace all covers and barriers; check for any pinched wires, and close doors. Make certain all enclosure parts are aligned properly and securely fastened.

Ground Fault Protection Systems

Paragraph 230-95(c) of the National Electrical Code requires that all equipment ground-fault protection systems be tested when first installed. If the circuit breaker has equipment ground-fault protection installed, test it at this time.

1. Make sure the trip unit is powered. The trip unit is powered if:
   - — The circuit breaker is closed or bottom fed and has more than 100 V of load voltage on two phases (P or H trip unit only).
   - — The full-function or hand-held test kit is connected and on.
   - — The 24 Vdc external power supply is connected.
   - — An external voltage tap is installed and voltage of more than 100 V is present on two phases (P or H trip unit only).
2. If the system is a radial (single-ended) system, press the ground-fault Push-to-Test button. The circuit breaker trips, and the trip unit ground-fault indicator light comes on.
3. Record results on the ground fault system test log.

NOTE: If a complete check of the ground-fault system is necessary, use primary injection testing. If the system is multiple source and/or requires field connections at the job site, use primary injection testing.

NOTE: Some ground fault systems require field connections at the job site. Consult the switchboard interconnection wiring drawing for details.

Section 6—Energizing the Switchboard

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Correct short-circuit conditions detected during the checkout procedures described in “Section 5—Pre-energizing Checkout Procedure” beginning on page 38.
- Qualified electrical personnel must be present when energizing this equipment for the first time.
- Follow the instructions in this section to energize the switchboard properly.

Failure to follow these instructions will result in death or serious injury.

1. Make sure there is not a load on the switchboard when it is energized. Turn off all downstream loads.
2. Energize the switchboard in the following sequence:
   a. Turn on all control power disconnects before energizing the switchboard. Refer to the record drawings supplied with equipment to see if control power disconnects are supplied.
   b. Close any open doors and/or covers.
   c. Close all main devices.
   d. Close each branch circuit breaker or branch fusible switch.
   e. Proceed to each panelboard and other downstream load.
3. After all overcurrent protective devices are closed, turn on all loads (for example, lighting circuits, contactors, heaters, and motors).

Section 7—Maintaining the Switchboard

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Inspect and perform preventive maintenance only on switchboards and equipment that has been de-energized and electrically isolated (unless otherwise specified). This helps ensure that accidental contact cannot be made with energized parts.
- Follow safety-related work practices as described in NFPA 70E, Part II at all times.

Failure to follow these instructions will result in death or serious injury.

Periodic maintenance of the switchboard includes cleaning, lubrication, and exercising component parts. The interval between maintenance checks can vary depending upon the amount of usage and environmental conditions of each installation. The maximum recommended inspection interval is one year. This definition for periodic maintenance applies throughout this manual, unless otherwise noted.

Always inspect the switchboard after a fault. (Refer to “Section 8—Adverse Circumstances”, beginning on page 50). Service bulletins for the various disconnecting and overcurrent devices mounted in the switchboard are available through your local Schneider Electric representative.

General Inspection and Cleaning

1. Vacuum the switchboard interior to remove any dirt or dust deposits. Wipe all bus bars, insulators, cables, etc., with a clean, dry, lint-free cloth.
2. Check the switchboard interior carefully for moisture, condensation build-up, or signs of any previous wetness. Moisture can cause insulation failures and rapid oxidation of current-carrying parts. Inspect all conduit entrances and cracks between the enclosure panels for dripping leaks. Condensation in conduits can be a source of moisture and must not be allowed to drip onto live parts or insulating material. Take the necessary steps to eliminate the moisture and seal off all leaks.

NOTICE

HAZARD OF EQUIPMENT DAMAGE

- Do not use an air hose to blow out the switchboard. Dust can settle inside relays and overcurrent devices, causing overheating and improper operation.
- Do not allow paint, chemicals, or petroleum-based solvents to contact plastics or insulating materials.

Failure to follow these instructions can result in equipment damage.

3. Inspect the switchboard for any signs of overheating. Discoloration and flaking of insulation or metal parts are indications of overheating.

   NOTE: If overheating occurs, be sure that all conditions that caused the overheating have been corrected. Loose or contaminated connections can cause overheating.

© 1988–2015 Schneider Electric All Rights Reserved

4. Check for signs of rodent nesting in the switchboard. If required, use a good exterminating technique in the general area of the switchboard.

   NOTE: Do not place or use exterminating substances and chemicals inside the switchboard. Some products attract rodents.
5. Carefully inspect all devices for any visibly worn-out, cracked, or missing parts.
6. Manually open and close switches and circuit breakers several times to verify they are working properly.
7. Verify that all key interlocks and door interlocking provisions are working properly.

Bus Bar Joints, Lug Terminations, and Insulating Materials

1. Bus bar joints are maintenance-free. Do not retighten them after the pre-energizing checkout procedure is complete.

NOTICE
HAZARD OF EQUIPMENT DAMAGE • Do not sand or remove plating on any bus bar, splice bar, or terminal lug. • Damage to plating can result in overheating. Replace damaged part. Contact Schneider Electric Services at 1-888-778-2733 (US) or 1-800-565-6699 (Canada). **Failure to follow these instructions can result in equipment damage.**

2. Check all bus bar joints and terminal lugs for any pitting, corrosion, or discoloration resulting from high temperatures or subjection to high fault conditions. If any damage has occurred, replace the bus bars or lugs. If cleaning is required, use Lectra-Clean®, made by CRC.
3. Inspect all insulating materials. Before re-energizing the switchboard, replace insulators with any visible damage (such as cracks).

General Lubrication Information

For field maintenance re-lubrication of blade/jaw components in switches 600 V and below, use BG20 High Performance Synthetic Grease from Dow Corning (Schneider Electric catalog number SWLUB). This grease is applicable for the following switches:

- Bolt-Loc
- QMB Main and Branch
- QMJ Branch
- QMQB[1] Main and Branch

For bus/plug-on connections, use electric joint compound, Schneider Electric catalog number PJC7201.

For Masterpact™ NW drawout connections, use only Schneider Electric catalog number S48899 Electric Joint Compound.

Automatic Transfer Switches

Consult the documentation provided by the manufacturer for all installation, operation, and maintenance instructions for these devices.

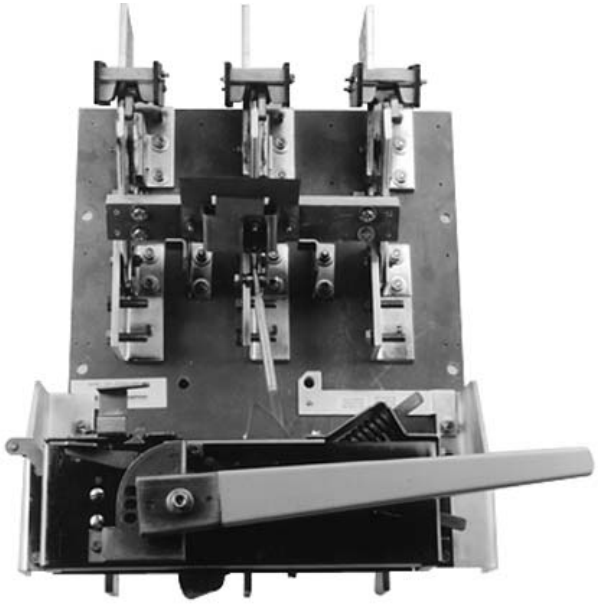
Bolt-Loc Bolted Pressure Contact Switch Maintenance (800–4,000 A)

Refer to the Bolt-Loc switch installation and maintenance manual for complete information (manual is shipped with the switchboard). If the manual is not available, refer to “Section 11—Reference Publications” on page 56, and contact your local Schneider Electric representative to obtain the appropriate manuals.

1. Exercise the operating mechanism at least once a year to ensure proper operation.
2. The Bolt-Loc switch is shipped from the factory properly lubricated. Periodic cleaning and lubrication of the switch is required. The maintenance interval between lubrications depends on factors such as usage and ambient conditions. The maximum recommended maintenance interval is one year for current-carrying parts and five years for operating mechanisms.

⚠ DANGER



HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Always check line and load ends of the fuses for voltage before starting the replacement procedure. The Bolt-Loc switch can be part of a multiple source system in which the fuses can be energized when the Bolt-Loc switch is in the “open” position.

Failure to follow these instructions will result in death or serious injury.

3. To replace the fuse:
   a. Open the switch before opening the fuse door.

Figure 29 – Type BP Bolt-Loc Fusible Switch

   b. Open the fuse door, releasing the interlock as described in the instructions on the door.
   c. Observe the switch blades to confirm the switch is “open.”
   d. Check the line and load ends of fuses for voltage using a properly rated voltage sensing device. No voltage should be present.

© 1988–2015 Schneider Electric All Rights Reserved

e. Remove all fuses. Retain the hardware for reuse.

f. Using a non-abrasive cleaner such as Lectra-Clean, made by CRC, wipe clean the fuse mounting pads on the switch and the terminals of each new fuse. Check the alignment of fuse terminals before installing new fuses.

g. Install new fuses using the same hardware removed in Step e. Tighten to 21–30 lb-ft (28–41 N•m).

4. Close the fuse door, and check the fuse door interlock with the switch in the ON position. The fuse doors should not open using normal hand force.

Circuit Breakers

Schneider Electric circuit breakers are designed and manufactured as sealed units requiring minimal periodic maintenance.

Exercise circuit breakers at least once a year to ensure proper operation. For general maintenance:

1. Trip the circuit breaker by pushing the Push-To-Trip or “Open” button located on the face of the circuit breaker. Refer to the appropriate circuit breaker manual for the specific location of this button.
2. Manually open and close the circuit breaker two to three times.

Figure 30 – PowerPact™ R-Frame Circuit Breaker

NOTE: Schneider Electric instruction bulletin 48049-900-0x, *Field Testing and Maintenance Guide for Thermal-Magnetic and Micrologic™ Electronic Trip Molded Case Circuit Breakers*, provides more in-depth information.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- If adjusting circuit breaker settings, do not set the long-time trip rating at a higher ampacity than the rating of the bus bar or load cables it supplies; overheating can occur.
- Before energizing the switchboard, fill all unused I-Line circuit breaker mounting spaces with blank fillers and/or extensions as listed in Table 3.

Failure to follow these instructions will result in death or serious injury.

Refer to individual circuit breaker instruction manuals shipped with the switchboard for additional maintenance information, such as changing rating plugs, sensor plugs, or adjustable settings and removing circuit breakers. If the instruction manual is not available, refer to “Section 11—Reference Publications” on page 56 for the appropriate number, or contact your local Schneider Electric representative.

NOTICE

HAZARD OF EQUIPMENT DAMAGE

- Do not remove the protective lubricant on the plug-on connectors.
- If additional lubrication is required, apply a coating of electrical joint compound, catalog number PJC7201, to the contact surfaces of the plug-on connector.

Failure to follow these instructions can result in equipment damage.

3. The universal test set, catalog number UTS3, is available to test Schneider Electric Powerpact P and R circuit breakers equipped with Micrologic trip units. It runs trip unit tests automatically, with prompts to the user for initial information. Test modules for each circuit breaker frame are used to store data necessary for automatic tests. Series B Micrologic trip units require test module CBTMB, which is included in UTS3.

   A pocket tester, catalog number S434206, or UTA tester, catalog number STRV00910, are available for Schneider Electric Powerpact H, J, and L circuit breakers with Micrologic trip units. These testers supply power to the Micrologic trip units and allow for settings to be adjusted through the keypad located on the circuit breaker or through a PC using the USB interface.

© 1988–2015 Schneider Electric All Rights Reserved

Masterpact NW trip units require the full-function test set, catalog number S33595, or the hand-held test set, catalog number S33594.

NOTE: Tests can be conducted with a circuit breaker installed in the switchboard; circuit breaker removal is not required. **The switchboard must be de-energized.**

QMB/QMJ/QMQB[1] Fusible Switches

Refer to the QMB/QMJ/QMQB[1] instruction manual for complete maintenance information. If the instruction manual is not available, refer to "Section 11—Reference Publications" on page 56 of this manual for the appropriate number. Contact your local Schneider Electric representative to obtain the manual.

Switch Maintenance

1. Periodically exercise the switch to ensure proper operation. This period should not exceed one year.
2. Check the cover interlock with the switch in the ON position. The cover should not open using normal hand force.
3. Inspect the switch interior for any damaged or cracked parts, and replace as necessary.
4. For fusible switch units, check the fuse mounting clips or bolted contact area for corrosion or discoloration (indicating overheating). Replace them if necessary.
5. For additional maintenance instructions, see the label on the inside of the door.

Fuse Replacement (Fusible Switches Only)

1. Turn the switch to the OFF position before opening the door.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Always check line and load ends of the fuses for voltage before starting the fuse replacement procedure with a properly rated voltage sensing device.

Failure to follow these instructions will result in death or serious injury.

2. Observe the switch blades to confirm that the switch is in the OFF position.
3. Using a properly rated voltage sensing device, verify that line and load ends of the fuse are not energized.
4. Observe all warning labels specifying the type of fuse to use. Do not substitute a non-current limiting fuse, or attempt in any way to defeat the rejection feature of the fuse clips furnished with the switch. Do not use renewable link fuses in Schneider Electric fusible switches.

NOTICE

HAZARD OF EQUIPMENT DAMAGE

Do not pry open or spread the fuse mounting clips. Doing so can cause a loose connection, resulting in overheating and nuisance fuse blowing.

Failure to follow these instructions can result in equipment damage.

Installing QMB/QMJ/QMQB[1] Fusible Switches

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Remove power for these sections before installing or removing QMB/QMJ/QMQB[1] switches.
- Do not use a main as a branch unit or a branch as a main.
- All unused spaces must be filled with blank fillers before energizing the switchboard. Refer to Tables 4 and 5 for sizes and catalog numbers.

Failure to follow these instructions will result in death or serious injury.

Table 4 – QMB/QMJ Fusible Switch Blank Fillers

Height	Catalog No.
1.50 in. (38 mm)	QMB1BLW
3.00 in. (76 mm)	QMB3BLW
6.00 in. (152 mm)	QMB6BLW
15.00 in. (381 mm)	QMB15BLW

Table 5 – QMQB[1] Fusible Switch Blank Fillers

Height	Catalog No.
2x: 1.375 in. (35 mm)	QFS1
8x: 5.50 in. (140 mm)	QFS5
10x: 6.875 in. (175 mm)	QFS6
14x: 9.625 in. (244 mm)	QFS9
24x: 16.50 in. (419 mm)	QFS16

NOTICE

HAZARD OF EQUIPMENT DAMAGE

Do not remove the protective lubricant on the plug-on connectors.

Failure to follow these instructions can result in equipment damage.

1. Turn off the main power.
2. Turn the switch handle(s) to the OFF position. Align switch plug-on connectors with QMB panel vertical bus, and plug switch onto panel.
3. Place and partially tighten all unit mounting screws that mount to the QMB panel mounting rails.
4. Tighten all screws evenly. The unit mounting flange and plug-on connectors must be seated securely.

 © 1988–2015 Schneider Electric All Rights Reserved

Removing QMB/QMJ/QMQB[1] Fusible Switches

1. Turn off the main power.
2. Turn switch handle(s) to the OFF position.
3. Disconnect the load wires.
4. For QMB and QMJ switches, remove mounting screws holding the switch to the mounting rail. For QMQB[1] switches, remove the bolts holding the switch to the line terminal.
5. Unplug the switch.

Ground-Fault Protection Systems

Check the terminal connections on the ground-fault protection system at least once a year for tightness and corrosion. If the system can be tested without tripping the main or branch device, directions for testing the system are in the device manual. Otherwise, testing the ground-fault protection system will trip the main or branch device to which it is connected. If the ground-fault sensor or relay is physically or electrically damaged, replace it.

If the ground-fault protection system does not operate properly and additional equipment has been connected to the installation since the last maintenance test/check, de-energize the entire system, and check for grounds on the neutral downstream from the main bonding jumper. If no downstream grounds are detected and the ground fault system is not operating properly, contact Schneider Electric Services at 1-888-778-2733 (US) or 1-800-565-6699 (Canada).

If no additions have been made to the installation and the ground-fault protection system does not operate properly, contact Schneider Electric Services at 1-888-778-2733 (US) or 1-800-565-6699 (Canada).

Refer to the ground-fault field test instruction manual for additional testing information. If the manual is not available, refer to “Section 11—Reference Publications” on page 56 of this manual to obtain the appropriate number. Contact your local Schneider Electric representative to obtain this manual.

Section 8—Adverse Circumstances

This section includes, but is not limited to, all electrical components of the switchboard.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Turn off all power supplying the switchboard before cleaning.
- Always use a properly rated voltage sensing device to confirm all power is off.
- Before energizing the switchboard, all unused circuit breaker mounting spaces must be filled.

Failure to follow these instructions will result in death or serious injury.

NOTE: Before attempting to re-energize the switchboard following adverse circumstances, contact Schneider Electric Services at 1-888-778-2733 (US) or 1-800-565-6699 (Canada) for special instructions.

Inspection Following a Short Circuit

If a short circuit occurs, make a thorough inspection of the entire system, and verify that no damage to conductors or insulation has occurred. High mechanical and thermal stresses developed by short-circuit currents can damage conductors and insulation. Check the overcurrent-protection device that interrupted the short-circuit current for possible arcing damage.

Do not open sealed devices, such as molded case circuit breakers. Replace these devices if they are damaged. Before energizing the switchboard, all unused circuit breaker mounting spaces must be filled. For more information about these devices, refer to the appropriate instruction manual listed in “Section 11—Reference Publications” on page 56.

Clean-up Following a Short Circuit

The insulating properties of some organic insulating materials can deteriorate during an electrical arc. If so:

1. Remove any soot or debris.
2. Replace carbon-tracked insulation.

Water-Soaked Switchboards

Do not clean or repair a switchboard that has been exposed to large volumes of water or submerged at any time. Current-carrying parts, insulation systems, and electrical components may be damaged beyond repair. **Do not energize the switchboard.** Contact Schneider Electric Services at 1-888-778-2733 (US) or 1-800-565-6699 (Canada).

© 1988–2015 Schneider Electric All Rights Reserved

Water-Sprayed or Splashed Switchboards (Clean Water Only)

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Turn off all power supplying this equipment before working on it.

Failure to follow these instructions will result in death or serious injury.

If the switchboard has been sprayed or splashed with small amounts of clean water, make a thorough inspection of the entire system, and verify that no damage to conductors or insulation has occurred. Do not open sealed devices such as molded case circuit breakers or fuses. Replace these devices if they are damaged. For more information about these devices, refer to the appropriate instruction manual listed in “Section 11—Reference Publications”.

Inspection and Clean-up of Clean Water Sprayed or Splashed Switchboards

Follow steps 1–10 only if:

- No signs of physical damage to the equipment are present.
- The switchboard has not been submerged or exposed to water for long periods of time.
- The water that has been in contact with the switchboard has not been contaminated with sewage, chemicals, or other substances that can negatively affect the integrity of the electrical equipment.
- The water that has been in contact with the switchboard has not entered any area of the enclosure that may contain wiring installed as intended and located above any live part. Specifically, inspect for water entering through conduits located above live parts.

If any one or more of these conditions have not been met, contact Schneider Electric Services at 1-888-778-2733 (US) or 1-800-565-6699 (Canada).

If **ALL** of the conditions listed have been met, proceed as follows:

1. Turn off all power supplying this equipment before working on or inside the equipment.
2. Always use a properly rated voltage sensing device to confirm all power is off.
3. Disconnect and electrically isolate the switchboard so that no contact can be made with energized parts.
4. Wipe off all moisture from the bus bars, insulators, and insulating material with a clean, dry, lint-free cloth. Do **not** use cleaning agents or water displacement sprays.
5. Prepare the switchboard for insulation resistance (Megger®) testing by disconnecting all line side supply connections and all load side cable connections to isolate the switchboard from the wiring system.

⚠ CAUTION

HAZARD OF EQUIPMENT DAMAGE OR INJURY

- Remove the long-time rating plug before electrical insulation testing a circuit breaker that has a label stating “Warning: Disconnect Plug Before Dielectric Test.”
- Some Micrologic trip units are not rated for voltages that would occur during electrical resistance insulation testing.
- Open all control and metering disconnects from the control circuits.

Failure to follow these instructions can result in injury or equipment damage.

6. Turn all circuit breakers or switches to their ON position. The switchboard must remain de-energized.
7. Use a megohmmeter with a capacity of 500–1,000 Vdc and apply voltage from:
   a. Each phase-to-ground with circuit breaker on.
   b. Phase-to-phase with circuit breaker on.
8. Record resistance values. Refer to “Section 10—Switchboard Insulation Resistance Chart” on page 55.
9. If resistance measurements are less than 0.5 megohm, call Schneider Electric Services at 1-888-778-2733 (US) or 1-800-565-6699 (Canada) for recommendations.
10. If resistance measurements are greater than 0.5 megohm, the equipment can be energized using the procedures listed in “Section 6—Energizing the Switchboard” on page 41.

Section 10—Switchboard Insulation Resistance Chart

Always use a 500 or 1,000 Vdc megohmmeter when testing insulation resistance.

NOTE: The Neutral–Ground column is provided to record the results of the pre-energizing checkout procedure only.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Turn off all power to the switchboard before testing.
- Always use a properly rated voltage sensing device to confirm power is off.

Failure to follow these instructions will result in death or serious injury.

Foreword

This publication is a guide of practical information containing instructions for the proper handling, installation, operation, and maintenance of deadfront distribution switchboards rated 600 Volts or less.

These instructions do not purport to cover all details or variations in equipment, nor to provide for every possible contingency regarding handling, installation, operation, or maintenance.

It is recommended that work described in this set of instructions be performed only by qualified personnel familiar with the construction and operation of switchboards and that such work be performed only after reading this complete set of instructions. For specific information not covered by these instructions, you are urged to contact the manufacturer of the switchboard directly.

PB 2.1-2013 revises and supersedes PB 2.1-2007.

In the preparation of this standards publication input of users and other interested parties has been sought and evaluated. Inquiries, comments, and proposed or recommended revisions should be submitted to the concerned NEMA product section by contacting the following:

Section 1
GENERAL

1.1 SCOPE

This publication covers floor-mounted deadfront switchboards which consist of an enclosure, molded case and low-voltage power circuit breakers, fusible or non-fusible switches, instruments, and metering, monitoring, or control equipment, with associated interconnections and supporting structures. These units are used in the distribution of electricity at:

a. 600 volts and less
b. 6000 amperes or less

1.3 GENERAL

WARNING—HAZARDOUS VOLTAGES IN ELECTRICAL EQUIPMENT CAN CAUSE SEVERE PERSONAL INJURY OR DEATH. UNLESS OTHERWISE SPECIFIED, INSPECTION AND MAINTENANCE SHOULD ONLY BE PERFORMED ON SWITCHBOARDS AND EQUIPMENT TO WHICH POWER HAS BEEN TURNED OFF, DISCONNECTED, AND ELECTRICALLY ISOLATED SO THAT NO ACCIDENTAL CONTACT CAN BE MADE WITH ENERGIZED PARTS. FOLLOW ALL MANUFACTURER'S WARNINGS AND INSTRUCTIONS.

Safety related work practices, as described in NFPA 70E, should be followed at all times.
All requirements of the *National Electrical Code®* NFPA 70 should be followed.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE SWITCHBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE SWITCHBOARD COMPONENTS DURING INSTALLATION OR MAINTENANCE.

1.3.1 Successful Operation

The successful operation of switchboards is dependent upon proper handling, installation, operation, and maintenance. Neglecting fundamental installation and maintenance requirements may lead to severe personal injury, death, or damage to electrical equipment or other property.

1.3.2 Qualified Personnel

Installation, operation, and maintenance of switchboards should be conducted only by qualified personnel.

1.3.3 Definition of Qualified Personnel

For purposes of these guidelines, a qualified person is one who is familiar with the installation, construction, and operation of the equipment and the hazards involved. In addition, the person is:

1.3.3.1 Knowledgeable of Requirements

Knowledgeable of the requirements of the *National Electrical Code*® and of all other applicable codes, laws, and standards.

1.3.3.2 Trained and Authorized to Test, Energize, Clear, Ground, Tag, and Lockout

Trained and authorized to test, energize, clear, ground, tag, and lockout circuits and equipment in accordance with established safety practices.

1.3.3.3 Trained in Proper Care and Use of Protective Equipment

Trained in the proper care and use of protective equipment such as rubber gloves, hard hat, safety glasses or face shields, and flash resistant clothing in accordance with established safety practices.

1.3.3.4 Trained in Rendering First Aid

Trained in rendering first aid.

Section 2
HANDLING

NOTE—These guidelines are provided to help avoid personal injury and equipment damage during handling and to facilitate moving the switchboard at the job site.

2.1 MANUFACTURER'S HANDLING INSTRUCTIONS

Follow the manufacturer's handling instructions for the specific equipment, if available.

2.2 CARE TO AVOID DAMAGE

Handle the switchboard with care to avoid damage to components, the frame or finish.

2.3 UPRIGHT POSITION

Keep the switchboard in an upright position unless otherwise indicated by the manufacturer.

2.4 EQUIPMENT CAPACITY

Verify that handling equipment capacity is sufficient for the switchboard weight.

2.5 CONCEALED DAMAGE

When the switchboard is received, unpack it sufficiently to inspect it for concealed damage and to determine that the shipment is complete and correct.

2.6 STORAGE PRIOR TO INSTALLATION

If the switchboard is to be stored prior to installation, replace the packing for protection during that period. When conditions permit, leave the packing intact until the switchboard or sections are at their final installation location. If the packing is removed, cover the top and any openings to protect the equipment against dust and debris during the construction period. (See section 3).

2.7 SHIPPING SKID

The switchboard should remain secured to the shipping skid to prevent distortion of the bottom of the frame during moving.

2.8 ROD OR PIPE ROLLERS

Rod or pipe rollers, with the aid of pinch bars, provide a simple method of moving the switchboard on one floor level if there is little or no incline. Steady the load to prevent tipping.

2.9 FORKLIFT TRUCK

A forklift truck may offer a more convenient method of handling the switchboard and has the added advantage of permitting it to be hoisted between levels. Balance the load carefully and use a safety strap when handling or moving switchboards with a forklift.

© 2014 National Electrical Manufacturers Association

2.10 OVERHEAD HOISTING

When it is necessary to move the switchboard between elevations without a suitable platform elevator, overhead hoisting may be required. Lifting plates and eye bolts (Figure 2-1), or channels, angles, or bars with lift holes (Figure 2-2) may be provided as a permanent or removable part of the switchboard. If they are not, cable, chain, or band slings (Figure 2-3) may be rigged around the switchboard.

2.10.1 Rigid Spreaders or Spanner Bars

Use rigid spreaders (Figure 2-1) or spanner bars (Figure 2-3) to provide the vertical lift on eye bolts and lifting slings to avoid crushing or otherwise damaging the frame or its finish. Lifting bars on long lineups may require additional spreaders to reduce the horizontal compressive force.

2.10.2 Rigging Lengths

Select or adjust the rigging lengths to compensate for any unequal weight distribution of load and to maintain the switchboard in an upright position.

2.10.3 Angle between Lifting Cables and Vertical

Do not allow the angle between the lifting cables and vertical to exceed 45 degrees in order to reduce the tension on the rigging and the compressive load on the lifting or spanner bars and spreaders.

2.10.4 Slings with Safety Hooks or Shackles

Do not pass ropes or cables through the lift holes in bars, angles, or channels. Use slings with safety hooks or shackles.

2.10.5 Removal of Switchboard Top Covers

The switchboard may contain a heavy transformer with overhead lifting means. Consult the manufacturer regarding the removal of the switchboard top covers and the utilization of such internal lifting means.

Section 3
STORAGE

3.1 CLEAN, DRY SPACE HAVING UNIFORM TEMPERATURE

A switchboard that is not installed and energized immediately should be stored in a clean, dry space having a uniform temperature to prevent condensation. Preferably, it should be stored in a heated building having adequate air circulation and protected from dirt, fumes, water, and physical damage.

3.2 PROTECTION FROM WEATHER AND DIRT

It is recommended that switchboards should not be stored outdoors. However, if it must be stored outdoors, cover it securely to provide protection from weather and dirt. Temporary electrical heating should be installed to prevent condensation; approximately 250 watts per section is adequate for the average switchboard size and environment. All loose packing or flammable materials inside the switchboard should be removed before energizing space heaters.

3.3 OUTDOOR SWITCHBOARDS ARE NOT WEATHER RESISTANT UNTIL INSTALLED

Outdoor switchboards are not weather resistant until completely and properly installed and should be treated exactly the same as indoor switchboards until after they are installed.

3.4 UN-ENERGIZED OUTDOOR SWITCHBOARD SHOULD BE KEPT DRY INTERNALLY

An un-energized outdoor switchboard should be kept dry internally by installing temporary heating (see 3.2) or by energizing any self-contained space heaters.

Section 4
INSTALLATION OF SWITCHBOARD OR ENCLOSURE

4.1 MANUFACTURER'S INSTALLATION INSTRUCTIONS

Install the switchboard in a neat and workmanlike manner following the manufacturer's installation instructions, if available.

4.2 LOCATION

Locate the switchboard in the area indicated on the building plans. The switchboard enclosure should be suitable for the environment or protected by other means. Additional precautions may be necessary, during installation, to prevent moisture, water, or other contaminants from entering and accumulating within the enclosures. Clearances or working spaces are as follows:

4.2.1 Clearance from Walls

Clearance from walls (not rear accessible)—minimum of 1/2 inch.

4.2.2 Working Clearances

Working clearances vary substantially depending on voltage and specific applications. See Section 110.26 of the *National Electrical Code®.*

NOTE—Spaces for working clearances and clearances from walls should not be used for storage. Working spaces should have adequate lighting.

4.3 CHANNEL SILLS

When channel sills are used, they should be embedded in the concrete floor or grouted on the surface. In either case, they should be installed in an aligned position and be level over the entire length prior to installing the switchboard.

4.4 CONDUIT AND OTHER RACEWAYS

Position the switchboard so that the raceway stubs or floor openings are located in the area specified on the manufacturer's drawing. In the absence of drawings, locate the switchboard over the raceways or floor openings so as to provide cable bending space and clearances to energized parts or other obstructions. See Section 408.5 of the *National Electrical Code®*.

4.5 LEVELING AND SECURING

Install the switchboard in its final position, progressively leveling each section and bolting the frames together if they are separated. If necessary, secure the switchboard to walls or other supporting surfaces. Security should not depend on wooden plugs driven into holes in masonry, concrete, plaster, or similar materials.

4.6 SPLICE BUS

Connect all through and ground bus at shipping breaks, using the splice bus and hardware supplied with the switchboard. Tighten bolted connections in accordance with the manufacturer's torque specifications. If not furnished, consult the manufacturer.

© 2014 National Electrical Manufacturers Association

4.7 GROUNDING AND BONDING

Ground and bond the switchboard as follows:

4.7.1 Grounded Systems

Switchboard used as service equipment for a grounded system or as a main switchboard for a separately derived system.

4.7.1.1 Grounding Electrode System in Switchboard

If the connection for the grounding electrode system is to be in the switchboard, install a grounding electrode conductor sized in accordance with Sections 250.66 or 250.166 of the *National Electrical Code*® from the grounding electrode to the switchboard ground bus or ground terminal designated by the manufacturer. See Sections 250.62 and 250.64 of the *National Electrical Code*®.

4.7.1.2 Switchboards Used as Service Equipment on Grounded Systems

Switchboards used as service equipment on systems that are grounded at any point are required to have a grounded conductor brought to the switchboard in accordance with Section 250.24(C) of the *National Electrical Code*®. This conductor is required even if the switchboard is supplying loads that are only phase-to-phase connected.

4.7.1.3 Installation of Main Bonding Jumper

Unless already done at the factory, install the main bonding jumper from the incoming grounded conductor bus (neutral) to the ground bus or other location designated by the manufacturer.

4.7.1.4 Steps 4.7.1.1 Through 4.7.1.3

Steps 4.7.1.1 through 4.7.1.3 must effectively connect together the grounding electrode, the switchboard frame, all outgoing equipment grounding conductors, and the grounded conductor bus (neutral) of the system on the supply side of any neutral disconnecting link.

4.7.1.5 Neutral Disconnecting Link

Do not connect any grounding conductors to the load side of any neutral disconnecting link or any sensor used for ground fault protection. Do not connect equipment grounding conductors directly to the grounded conductor bus (neutral).

4.7.1.6 Dual Fed Switchboard or System

Where the switchboard or system is dual fed (double-ended) and has ground fault protection, special precautions are necessary to accomplish proper grounding and bonding. Follow the manufacturer's instructions.

4.7.2 Ungrounded Systems—Service Equipment or Separately Derived System Main

4.7.2.1 Conductor Sized in Accordance with *National Electrical Code*®

Install a grounding electrode conductor sized in accordance with Sections 250.66 or 250.166 of the *National Electrical Code*® from the grounding electrode to the switchboard ground bus or ground terminal designated by the manufacturer. See Sections 250.62 and 250.64 of the *National Electrical Code*®. This should effectively connect together the grounding electrode, the switchboard frame, and all outgoing equipment grounding conductors.

4.7.3 Grounded or Ungrounded Systems

Applications other than service equipment or other than main for separately derived systems.

© 2014 National Electrical Manufacturers Association

4.7.3.1 Grounding Conductor Size in Accordance with *National Electrical Code*®

Ground the switchboard frame and any ground bus by means of an equipment grounding conductor having a size in accordance with Section 250.122 of the *National Electrical Code*® and run with the main supply conductors or by bonding to the raceway enclosing the main supply conductors in accordance with Sections 250.118 and 250.120 of the *National Electrical Code*®.

4.8 UNUSED OPENINGS

Effectively close all unused openings in the switchboard enclosure.

4.9 DAMP INDOOR LOCATIONS

In damp indoor locations, shield the switchboard so as to prevent moisture and water from entering and accumulating therein.

4.10 UNUSUAL SERVICE CONDITIONS

Unless the switchboard has been designed for unusual service conditions, it should not be located where it will be exposed to ambient temperatures above 40°C (104°F), high humidity, corrosive or explosive fumes, dust, vapors, dripping or standing water, abnormal vibration, mechanical shock, tilting, or other unusual operating conditions.

Section 5
INSTALLATION OF CONDUIT AND CONDUCTORS

5.1 PREVENT MOISTURE OR WATER FROM ENTERING

Conduits and other raceways should be installed to prevent moisture or water from entering and accumulating within the enclosure. All metallic raceways (including stubs) should be bonded to the switchboard. All raceways should be located in the areas recommended by the manufacturer to avoid conductor interference with structural members and live parts. Before pulling any conductors into the switchboard, verify that their size, temperature rating, and conductor insulation comply with the switchboard markings. See Section 110.14(C) of the *National Electrical Code*®.

5.2 TEMPERATURE RATINGS

Care should be exercised to ensure that the types and temperature ratings of conductors being installed in the switchboard are suitable for use with the terminals which have been provided.

5.3 COMPRESSION (CRIMP) TERMINALS

If compression (crimp) terminals are used, crimp with the tool(s) recommended by the manufacturer.

5.4 STRIPPING INSULATION FROM CONDUCTORS

Care should be exercised in stripping insulation from the conductors so as not to nick or ring the conductor. For aluminum, clean all oxide from the stripped portion and apply an oxide inhibiting compound. All mechanical terminals should be tightened per the manufacturer's torque specifications. If not furnished, consult the manufacturer.

5.5 PROPER WIRING METHODS

Refer to Article 300 of the *National Electrical Code*® for proper wiring methods. Conductors should enter the switchboard in the section in which they are to be terminated, except as noted in Section 408.3(A)(3) of the *National Electrical Code®.*

5.6 CONDUCTOR LOCATION IN SWITCHBOARD

Provision should be made to locate conductors in the switchboard so that they will be free from physical damage and to avoid overheating. If required by the manufacturer's instructions, secure the conductors as necessary in order to withstand short-circuit forces. The largest practical bending radii should be maintained to avoid damaging the insulation and causing terminals to loosen. Exercise care so that the conductors will not interfere with any moving parts.

5.7 CONDUCTORS 1/0 AWG IN SIZE AND LARGER

Conductors 1/0 AWG in size and larger may be run in parallel. All parallel conductors should be of the same size, length, and material to assure the equal division of current, as required by Section 310.10(H) of the *National Electrical Code*®. If conductors pass through metal having magnetic properties, all of the circuit conductors, including the neutral, should be run through the same opening, as specified by Section 300.20(A) of the *National Electrical Code*®.

© 2014 National Electrical Manufacturers Association

5.8 INCOMING AND OUTGOING CONTROL CONNECTIONS

All incoming and outgoing control connections should be made in accordance with the switchboard manufacturer's schematic and wiring diagrams.

5.9 PREVENT CONDUCTOR INSULATION FROM CRACKING OR SPLITTING

Installation of conductors should be done at temperatures above freezing to prevent conductor insulation from cracking or splitting, unless the conductor insulation is suitable for installation at temperatures below freezing.

5.10 *NATIONAL ELECTRICAL CODE*®, SECTION 725.136

Refer to the *National Electrical Code*®, Section 725.136 for the separation requirements for conductors of Class 2 and Class 3 remote control, signaling and power-limited circuits.

Section 6
INSTALLATION OF SWITCHBOARD INTERIOR

6.1 INSTRUCTIONS IF SWITCHBOARD INTERIOR WAS NOT FACTORY–MOUNTED

Follow these instructions if the switchboard interior(s) was not mounted at the factory.

6.2 UNPACKING

Exercise care in unpacking the switchboard interior to prevent damage.

6.3 INSPECTION

Check for shipping damage and check to make sure the interior is the correct one for the installation.

6.4 STORAGE

Store the switchboard interior in a clean dry place where it will not be subject to physical damage.

6.5 CLEANING

Clean the switchboard enclosure of all foreign material prior to the installation of the interior. If parts at connection points are splattered with cement, plaster, paint, or other foreign material, remove the foreign material with great care to avoid damage to the plating.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE SWITCHBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE SWITCHBOARD COMPONENTS DURING INSTALLATION OR MAINTENANCE.

6.6 MANUFACTURER'S INSTRUCTIONS

Carefully follow the switchboard manufacturer's instructions.

6.7 INTERIOR INSTALLATION

Install the interior and tighten it securely in the enclosure. Install the section bus connection to the through bus, if needed.

Section 7
STEPS TO BE TAKEN BEFORE ENERGIZING

7.1 ACCESSIBLE ELECTRICAL CONNECTIONS

Tighten all accessible electrical connections to the manufacturer's torque specifications. If such information is not provided with the equipment, consult the manufacturer.

7.2 BLOCKS OR OTHER TEMPORARY HOLDING MEANS

Remove all blocks or other temporary holding means used for shipment from all component devices and the switchboard interior.

7.3 INTEGRITY OF ALL BUS MOUNTING MEANS

Check the integrity of all bus mounting means.

7.4 ENCLOSURE

Check the enclosure to see that it has not been damaged in such a manner as to reduce electrical spacings.

7.5 OPERATING MECHANISMS

Manually exercise all switches, circuit breakers, and other operating mechanisms to make certain that they operate freely.

Check the integrity of all electrical and mechanical interlocks and padlocking mechanisms. For key interlocked systems, assure that only the required number of keys are accessible to the operator

7.6 ELECTRICAL INSULATION RESISTANCE TEST

Conduct an electrical insulation resistance test to ensure that the switchboard is free from short circuit or ground fault conditions. With the neutral isolated from ground and the switches and circuit breakers open, conduct electrical insulation resistance tests from phase to phase, phase to ground, phase to neutral, and neutral to ground. If the resistance reads less than 1 megohm while testing with the branch circuit devices in the open position, the system may be unsafe and should be investigated. If after the investigation and possible corrections, low readings are still observed, the manufacturer should be contacted. Some electronic equipment (metering, SPD, etc.) may be damaged by this testing. Refer to the manufacturer’s equipment markings for guidelines.

7.7 ELECTRICAL RELAYS, METERS, AND INSTRUMENTATION

Check electrical relays, meters, and instrumentation to determine that connections are made properly and that the devices function properly.

7.8 ELECTRICALLY OPERATED SWITCHES, CIRCUIT BREAKERS, AND OTHER MECHANISMS

With loads disconnected, electrically exercise all electrically operated switches, circuit breakers, and other mechanisms to determine that the devices operate properly. An auxiliary source of control power may be necessary to provide power to the electrical operators.

© 2014 National Electrical Manufacturers Association

7.9 GROUND FAULT PROTECTION SYSTEM

Test the ground fault protection system (if furnished) in accordance with the manufacturer's instructions. See Section 230.95 of the *National Electrical Code*® and NEMA PB 2.2.

7.10 ADJUSTABLE TIME CURRENT TRIP DEVICE SETTINGS

Set any adjustable time current trip device settings to the proper values.

NOTE—Experience has indicated that damage from overcurrent can be reduced if the devices used for overload and short-circuit protection are set to operate instantaneously (that is, without intentional time delay) at 115 percent of the highest value of phase current which is likely to occur as the result of any anticipated motor starting or welding currents.

7.11 FIELD WIRING

Make certain that field wiring is clear of live parts and, when specified by the manufacturer, physically secured to withstand the effects of short circuits.

7.12 GROUNDING CONNECTIONS

Check to determine that all grounding connections are properly made. If the switchboard is used as service equipment, make certain that the neutral, if present, is properly bonded to the cabinet. If there is no ground bus, make certain that the sections of the switchboard which are shipped separately are connected in such a way as to ensure a continuous grounding path.

7.13 FOREIGN MATERIAL

Remove all foreign material from the inside of the switchboard before closing the enclosure.

7.14 COVERS AND DOORS

Install covers, close doors, and make certain that no conductors are pinched and that all enclosure parts are properly aligned and tightened. Hinged covers or doors must open a minimum of 90 degrees when installed.

Section 8
ENERGIZING EQUIPMENT

WARNING—HAZARDOUS VOLTAGES IN ELECTRICAL EQUIPMENT CAN CAUSE SEVERE PERSONAL INJURY OR DEATH. ENERGIZING A SWITCHBOARD FOR THE FIRST TIME AFTER INITIAL INSTALLATION OR MAINTENANCE IS POTENTIALLY DANGEROUS.

8.1 QUALIFIED PERSONNEL PRESENT

Only qualified personnel should energize equipment for the first time. If short circuit conditions caused by damage or poor installation practices have not been detected in the checkout procedure specified in Section 7, serious personal injury and damage can occur when the power is turned on.

8.2 NO LOAD ON SWITCHBOARD

There should be no load on the switchboard while it is being energized. Turn off all the downstream loads.

8.3 ENERGIZED IN SEQUENCE

The equipment should be energized in sequence by starting at the source end of the system and working towards the load end. In other words, energize the main devices, then the feeder devices, and then the branch-circuit devices. Turn the devices on with a firm positive motion.

8.4 AFTER ALL MAIN, FEEDER, AND BRANCH CIRCUIT DEVICES HAVE BEEN CLOSED

After all main, feeder, and branch circuit devices have been closed, loads such as lighting circuits, contactors, heaters, and motors may be turned on.

© 2014 National Electrical Manufacturers Association

Section 9
MAINTENANCE

9.1 MAINTENANCE PROGRAM FOR SWITCHBOARDS

A maintenance program for switchboards should be conducted on a regularly scheduled basis in accordance with the following:

9.2 FIELD TEST

A switchboard which has been carrying its regular load for at least 3 hours just prior to inspection should be field tested by feeling the deadfront surfaces of circuit breakers, switches, interior trims, doors, and enclosure sides with the palm of the hand. If the temperature of these surfaces does not permit you to maintain contact for at least 3 seconds, this may be an indication of trouble and investigation is necessary. Thermographic (infrared) scanning has become a useful method of investigating thermal performance.

WARNING—HAZARDOUS VOLTAGES IN ELECTRICAL EQUIPMENT CAN CAUSE SEVERE PERSONAL INJURY OR DEATH. UNLESS OTHERWISE SPECIFIED, INSPECTION AND MAINTENANCE SHOULD ONLY BE PERFORMED ON SWITCHBOARDS TO WHICH POWER HAS BEEN TURNED OFF, DISCONNECTED AND ELECTRICALLY ISOLATED SO THAT NO ACCIDENTAL CONTACT CAN BE MADE WITH ENERGIZED PARTS. FOLLOW ALL MANUFACTURER'S WARNINGS AND INSTRUCTIONS.

Safety related work practices, as described in NFPA 70E, should be followed at all times.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE SWITCHBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE SWITCHBOARD COMPONENTS DURING INSTALLATION OR MAINTENANCE.

9.3 SWITCHBOARD INSPECTION ONCE EACH YEAR

Inspect the switchboard once each year or after any severe short circuit.

9.4 ACCUMULATION OF DUST AND DIRT

If there is an accumulation of dust and dirt, clean out the switchboard by using a brush, vacuum cleaner, or clean lint-free rags. Avoid blowing dust into circuit breakers or other components. Do not use a blower or compressed air.

9.4.1 All Visible Electrical Joints and Terminals

Carefully inspect all visible electrical joints and terminals in the bus and wiring system.

9.4.2 All Conductors and Connections

Visually check all conductors and connections to be certain that they are clean and secure. Loose and/or contaminated connections increase electrical resistance which can cause overheating. Such overheating is indicated by discoloration or flaking of insulation and/or metal parts. Pitting or melting of connecting surfaces is a sign of arcing due to a loose, or otherwise poor connection. Parts which show evidence of overheating or looseness should be cleaned and re-torqued or replaced if damaged. Tighten bolts and nuts at bus joints to manufacturer's torque specifications.

© 2014 National Electrical Manufacturers Association

CAUTION—DO NOT REMOVE PLATING FROM ALUMINUM PARTS IN JOINTS OR TERMINATIONS. DAMAGE TO PLATING CAN RESULT IN OVERHEATING. REPLACE DAMAGED ALUMINUM PARTS.

9.4.3 Fuse Clip Contact Pressure and Contact Means

Examine fuse clip contact pressure and contact means. If there is any sign of overheating or looseness follow the manufacturer's maintenance instructions or replace the fuse clips. Loose fuse clips can result in overheating.

9.4.4 All Conditions Which Caused Overheating

Be sure that all conditions which caused the overheating have been corrected.

9.5 PROPER AMPERE, VOLTAGE, AND INTERRUPTING RATINGS

Check circuit breakers, switches, and fuses to ensure they have the proper ampere, voltage, and interrupting ratings. Ensure that non-current-limiting devices are not used as replacements for current-limiting devices. Never attempt to defeat rejection mechanisms which are provided to prevent the installation of the incorrect class of fuse.

9.5.1 All Mechanisms Are Free and in Proper Working Order

Operate each switch or circuit breaker several times to ensure that all mechanisms are free and in proper working order. Replace as required. See NEMA AB 4 for maintenance of molded case circuit breakers.

9.6 OPERATION OF ALL MECHANICAL COMPONENTS

Check the operation of all mechanical components. Replace as required.

9.6.1 Full On and Off Positions

Exercise switch operating mechanisms and external operators for circuit breakers to determine that they operate freely to their full on and off positions.

9.6.2 Integrity of Electrical and Mechanical Interlocks

Check the integrity of all electrical and mechanical interlocks and padlocking mechanisms. For key interlocked systems, assure that only the required number of keys are accessible to the operator.

9.6.3 Missing or Broken Parts

Whenever practical, check all devices for missing or broken parts, proper spring tension, free movement, corrosion, dirt, and excessive wear.

9.6.4 Manufacturer's Instructions

Adjust, clean, and lubricate or replace parts according to the manufacturer's instructions.

9.6.4.1 Clean, Nonmetallic, Light, Grease or Oil

Use clean, nonmetallic, light grease or oil as instructed.

9.6.4.2 Molded Case Circuit Breakers

Do not oil or grease parts of molded case circuit breakers.

9.6.4.3 Lubrication with Clean, Light Grease

If no instructions are given on the devices, sliding copper contacts, operating mechanisms, and interlocks, they may be lubricated with clean, light grease.

© 2014 National Electrical Manufacturers Association

9.6.4.4 Excess Lubrication

Wipe off excess lubrication to avoid contamination.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE SWITCHBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE SWITCHBOARD COMPONENTS DURING INSTALLATION OR MAINTENANCE.

9.6.5 Readily Accessible Copper Electrical Contacts, Blades, and Jaws

Clean and dress readily accessible copper electrical contacts, blades, and jaws according to the manufacturer's instructions when inspection indicates the need.

9.7 DETERIORATED INSULATING MATERIAL AND ASSEMBLIES

Look for and replace deteriorated insulating material and assemblies where sealing compounds have melted.

9.8 MOISTURE OR SIGNS OF PREVIOUS WETNESS

Look for any moisture or signs of previous wetness or dripping inside the switchboard.

NOTE—Condensation in conduits or dripping from outside sources is one known cause of switchboard malfunction.

9.8.1 Conduits Which Have Dripped Condensate

Seal off any conduits which have dripped condensate, and provide means for further condensate to drain away from the switchboard.

9.8.2 Cracks or Openings

Seal off any cracks or openings which have allowed moisture to enter the enclosure. Eliminate the source of any dripping on the enclosure and any other source of moisture.

9.8.3 Insulating Material Which is Damp

Replace or thoroughly dry and clean any insulating material which is damp or wet or shows an accumulation of deposited material from previous wettings.

9.8.4 Moisture Damaged Component Device

Inspect all component devices. Replace any component device which shows evidence of moisture damage or has been subjected to water damage or flooding. Additional information may be found in the NEMA document “Guidelines for Handling Water Damaged Electrical Equipment”.

9.9 WATER DAMAGE

In the event of water damage, e.g., flooding or sprinkler discharge, the manufacturer should be consulted before clean up and corrective action is attempted.

9.10 SEVERE ELECTRICAL SHORT CIRCUIT

If a severe electrical short circuit has occurred, the excessive currents may have resulted in structural component and/or bus and conductor damage due to mechanical distortion, thermal damage, metal deposits, or smoke. Examine all devices and bus supports for cracks or breakage. The manufacturer should be consulted before clean up and correction is attempted.

© 2014 National Electrical Manufacturers Association

9.11 GROUND FAULT PROTECTION SYSTEM

Test the ground fault protection system (if furnished) in accordance with the manufacturer's instructions. See Section 230.95 of the *National Electrical Code*® and NEMA Standards Publication PB 2.2.

9.12 INSULATION RESISTANCE

Check insulation resistance (See 7.6) under any of the following conditions:

a. If a severe short circuit has occurred. (See 9.10)
b. If it has been necessary to replace parts or clean insulating surfaces
c. If the switchboard has been exposed to high humidity, condensation, or dripping moisture.

Section 10
PERMISSIBLE LOADING OF SWITCHBOARDS

10.1 SWITCHBOARDS WITHOUT MAIN OVERCURRENT PROTECTIVE DEVICES

For switchboards without main overcurrent protective devices (main lug switchboard), the total continuous load current through the supply bus should not exceed the current rating of the switchboard.

10.2 SWITCHBOARDS WITH A SINGLE MAIN OVERCURRENT PROTECTIVE DEVICE

For switchboards with a single main overcurrent protective device, the total continuous load current on the protective device should not exceed 80 percent of its ampere rating unless the device is rated to carry 100 percent of its ampere rating.

10.3 SWITCHBOARDS WITH A MULTIPLE MAIN OVERCURRENT PROTECTIVE DEVICE

For switchboards with a multiple main overcurrent protective devices, the total continuous current through the supply bus should not exceed the current rating of the switchboard. The total continuous load current on each main overcurrent protective device should not exceed 80 percent of its ampere rating unless the device is rated to carry 100 percent of its ampere rating.

10.4 FEEDER AND BRANCH CIRCUIT OVERCURRENT PROTECTIVE DEVICES IN SWITCHBOARDS

For feeder and branch circuit overcurrent protective devices in switchboards, the total continuous load current on the overcurrent protective device should not exceed 80 percent of its ampere rating unless the device is rated to carry 100 percent of its ampere rating.

10.5 HARMONICS IN THE ELECTRICAL SYSTEM

Some types of electrical equipment cause harmonics in the electrical system which may result in overheating. This condition should be considered when determining switchboard loading.

Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

⚠ CAUTION

LOSS OF BRANCH CIRCUIT POWER/LOSS OF SURGE SUPPRESSION

- Perform periodic inspection of the Surge Protective Device status indicator lights as part of the preventative maintenance schedule.
- Promptly service the Surge Protective Device when an alarm state exists.
- Use dry contacts to signal an alarm state to the central supervisory system for unmanned, inaccessible, or critical installations.
- Use multiple Surge Protective Devices to achieve redundancy for critical applications.

Failure to follow these instructions can result in injury or equipment damage.

At end-of-life conditions, Surge Protective Devices (SPDs) can lose their ability to block power system voltage and attempt to draw excessive current from the line. This SPD is equipped with overcurrent and overtemperature components that disconnect the surge suppression elements from the electrical supply should the surge suppression elements reach end of life. Tripping of the branch circuit breaker or fuse feeding the SPD can occur when the surge suppression elements reach end of life.

ENGLISH

⚠ CAUTION

LOSS OF SURGE SUPPRESSION

- Do not energize the Surge Protective Devices until the electrical system is completely installed, inspected, tested, and all conductors have been connected and functional, including the neutral.
- Verify the voltage rating of the device and system before energizing the Surge Protective Device.
- Perform high-potential insulation testing, or any other tests where Surge Protective Device components will be subjected to voltages higher than their rated turn-on voltage, with the neutral and Surge Protective Device disconnected from the power source.

Failure to follow these instructions can result in injury or equipment damage.

Introduction

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

Note: For troubleshooting, call the Surgelogic Technical Assistance Group at 1-800-577-7353.

Proper installation is imperative to maximize the IMA SPD's effectiveness and performance. Follow the steps outlined in this instruction bulletin to ensure proper installation. Read the entire instruction bulletin before beginning the installation. These instructions are not intended to replace national or local electrical codes. Check all applicable electrical codes to verify compliance. Installation of IMA surge suppressors should only be performed by qualified electrical personnel.

Unpacking and Preliminary Inspection

Inspect the entire shipping container for damage or signs of mishandling before unpacking the device. Remove the packing material and further inspect the device for any obvious shipping damage. If any damage is found and is a result of shipping or handling, immediately file a claim with the shipping company.

© 2002–2016 Schneider Electric All Rights Reserved

Storage

The device should be stored in a clean, dry environment. Storage temperature is -40 °F to +149 °F (-40°C to +65°C). All of the packaging materials should be left intact until the device is ready for installation.

Safety Labels

English, Spanish, and French versions of all safety labels (Danger, Warning, and Caution) are provided.

Location Considerations

Environment

The device is designed to operate in an ambient temperature range of -4 °F to +149 °F (-20°C to +65°C) with a relative humidity of 0 to 95% non-condensing. The operating temperature of the LCD on the diagnostic display panel is +14 °F to +140 °F (-10°C to +60°C). Refer to the product catalog for further details on enclosures. All IMA devices operate normally without reduction in performance when subjected to shock and vibrations described in IEC 60721-3-3, Class 3M4.

Audible Noise

The device background noise is negligible and does not restrict the location of the installation.

Mounting

Refer to page 13 for typical mounting dimensions.

Service Clearance

The service clearance should meet all applicable code requirements.

Equipment Performance

To obtain the maximum system performance, locate the device as close to the circuit being addressed as possible, to minimize the interconnecting wiring length. For every foot of wire length, approximately 160 Volts (6 kV / 3 kA, 8/20 microsecond) is added to the suppressed voltage. The Voltage Protection Rating (VPR) is located on the device nameplate and is measured six inches from the enclosure sidewall, according to UL® 1449.

Electrical

Voltage Rating

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Confirm the Surge Protective Device voltage rating on the module or nameplate label is the same as the operating voltage.

Failure to follow these instructions will result in death or serious injury.

Prior to mounting the SPD, verify that the device has the same voltage rating as the power distribution system in which it is installed. Compare the nameplate voltage on the SPD with the nameplate voltage of the electrical distribution equipment.

© 2002–2016 Schneider Electric All Rights Reserved

ENGLISH

The specifier or user of the device must be familiar with the configuration and arrangement of the power distribution system in which any SPD is to be installed. The system configuration of any power distribution system is based strictly on how the secondary windings of the transformer supplying the service entrance main or load are configured. This includes whether or not the transformer windings are referenced to earth via a grounding conductor. The system configuration is not based on how any specific load or equipment is connected to a particular power distribution system. See Table 1 for the service voltage of each SPD.

Branch Circuit Overcurrent Protection

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Use conductors rated for the Overcurrent Protection Device (OCPD) per applicable codes.
- Use conductors rated for the application per applicable codes.

Failure to follow these instructions will result in death or serious injury.

UL 1449 Type 1 SPDs have been designed and approved for line side applications prior to the main service disconnect without supplemental overcurrent protection. Type 2 SPDs must be installed on the load side of the main Overcurrent Protection Device (OCPD). All installations should either provide or include a disconnecting means.

Location of Surge Protective Device (SPD)

Locate the SPD as close as possible to the circuit being addressed to minimize the wire length and optimize SPD performance. Avoid long wire runs so that the device will perform as intended. To reduce the impedance that the wire displays to surge currents, the phase, neutral, and ground conductors must be routed within the same conduit and tightly bundled or twisted together to optimize device performance. Avoid sharp bends in the conductors. See Figure 1.

Figure 1: Surge Protective Device Wiring Practice

Grounding

⚠ WARNING

HAZARDOUS TOUCH VOLTAGE

- Connect the Surge Protective Device ground terminal to the building grounding grid structure.
- Use an appropriately sized equipment grounding conductor.
- When using metallic raceway or conduit:
  - — Do not use isolation bushings to interrupt the metallic raceway or conduit.
  - — Maintain electrical continuity at all raceway and conduit connections using appropriate bonding devices.
- Do not use a separate isolated ground for the Internal Modular Assembly device.
- Verify proper equipment connection to the grounding system.
- Verify ground grid continuity by performing regularly scheduled inspections and testing as part of a comprehensive electrical maintenance program.

Failure to follow these instructions can result in death or serious injury.

General

The IMA has SPD elements connected from phase to ground. It is critical that there be a robust and effective connection to the building grounding structure. The grounding connection must utilize an equipment grounding conductor run with the phase and neutral connection of the power system. Do not connect the SPD to a separate isolated ground.

For best overvoltage suppression by the IMA SPD, use a single-point ground system where the service entrance grounding electrode system is connected to, and bonded to, all other available electrodes, building steel, metal water pipes, driven rods, etc. (for reference, see NEC Art 250). The ground impedance measurement of the electrical system should be as low as possible and in compliance with all applicable codes.

Power System Grounding

In addition to the power system configuration and voltage, the power system grounding method must be considered when selecting the appropriate IMA device. Refer to the following chart for information concerning the suitability of IMA device to specific power system grounding method.

Solidly-Grounded Power Systems

⚠CAUTION

SURGE PROTECTIVE DEVICE DAMAGE AND POWER SYSTEM OVERVOLTAGE

- Do not connect devices rated for use on solidly-grounded power systems to resistance-grounded (for example, High Resistance Ground) or ungrounded power systems.
- Verify that the service entrance equipment is bonded to ground in accordance with all applicable codes.
- Verify that the neutral terminal of the power system transformer feeding the device is bonded to system ground in accordance with all applicable codes.

Failure to follow these instructions can result in equipment damage.

SPDs rated for use on solidly-grounded power systems must not be connected to resistance-grounded or ungrounded power systems. Such a connection can result in damage to the SPD.

Always verify the power system grounding configuration prior to application of power to the device. Confirm that all ground bonds are installed at both the service entrance equipment and power system transformer prior to application of power.

Delta and Resistance-Grounded Power Systems

⚠ CAUTION

SURGE PROTECTIVE DEVICE DAMAGE AND POWER SYSTEM OVERVOLTAGE

- Ungrounded power systems are inherently unstable and can produce excessively high line-to-ground voltages during certain fault conditions. During these fault conditions any electrical equipment, including an SPD, may be subjected to voltages which exceed their designed ratings. This information is being provided to the user so that an informed decision can be made before installing any electrical equipment on an ungrounded power system.
- Resistance-grounded power systems must be maintained in an over-damped state to limit voltage overshoot and duration during operation.
- Verification and adjustment of correct power system damping should be done:
  - — Periodically as part of normal system maintenance.
  - — Following power system modifications.

Failure to follow these instructions can result in equipment damage.

The IMA product is intended for use on resistance-grounded power systems where the power system has been set for, and is maintained in, an over-damped state. For the power system to be over-damped, the current through the grounding resistor during a bolted phase-to-ground fault must be significantly greater than the total charging current of the system.

Periodic engineering evaluation of the power system is required to determine the worst-case charging current of the system and to adjust the grounding resistance accordingly. As the power system is modified, the value of the grounding resistor must be evaluated and adjusted to maintain the system in the over-damped state.

Installation

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

UL Conditions of Acceptability

For use only in equipment where the acceptability of the combination is determined by Underwriters Laboratories®. When installed in the end-use equipment, the following are among the considerations to be made:

1. A suitable electrical enclosure shall be provided in the end-use product.
2. The device is intended for factory wiring only with the suitability of the connections (including spacings between factory connectors) determined in the end-use application.
3. Voltage Protection Rating (VPR) shall be determined in the end-product where applicable.
4. The SPD unit has been subjected to the following tests of UL1449:
   a. Surge Testing (VPR)
   b. Nominal Discharge Test (20 kA)
   c. Operational Voltage Test
   d. Dielectric Voltage Withstand
   e. Current Tests (Short Circuit Current, Intermediate Currents, Limited Currents)
5. The component SPD has been evaluated to Short Circuit Rating tests (SCCR), per UL 1449) at 200 kA rms available fault current, without external Overcurrent Protective Devices (OCPD) or external enclosures.

Follow the steps listed below when making wiring connections:

1. Turn off all power supplying this equipment before working on or inside any enclosure containing this equipment.
2. Confirm the SPD voltage rating and configuration is the same as the system voltage and power system configuration to which it will be connected.
3. Identify proper location for surge protective device. Locate as close as possible to the panel being addressed so the wires are as short as possible. Mount unit securely.

   Note: The surge protective device must be installed in an accessible location as described in the NEC.
4. Install in accordance with national and local electrical codes for overcurrent protection recommendations and wire ampacity considerations.

   Note: The neutral connection is not present on three-wire, three-phase wye ground or two-wire single-phase mid-point ground power systems. For these systems, bond the neutral and ground lugs together in the SPD. For a High Resistance Ground (HRG) or Delta SPD, no neutral connection exists. For installation wiring see Figures 6 and 7.

   Note: See Terminals, Wire Size, and Installation Torque and Table 2 on page 7 for acceptable wire size and installation torque.
5. Twist conductors ½ turn or more for every twelve inches of length. Do not loop or coil wires. Be sure to maintain adequate wire bending space per NEC.
6. If the remote signaling contacts of the diagnostic display panel are to be used, refer to the section, “Dry Contacts”, on page 18 for wiring instructions.
7. On a High-Leg Delta installation, note the high leg connection per wiring diagram. See Figure 5.
8. Replace all devices, doors and covers before turning on power to the equipment. If the SPD is properly installed and functioning, the green LED indicators on the display will be lit.

For questions pertaining to the installation of this device, contact the Surgelogic Technical Assistance Group at 1-800-577-7353.

Operation

⚠ DANGER

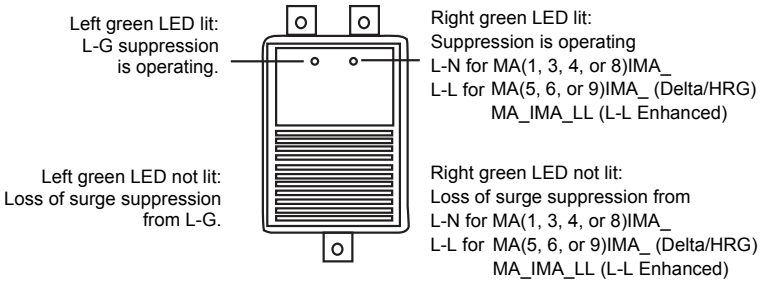
HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

LED Status Indicators

The SPD diagnostic display panel shows the status of each MA module with diagnostically controlled green/red LEDs (see Figure 8). If a unit is operating correctly, all of the phase LEDs will be illuminated green. To test the integrity of the diagnostics for each phase, push the button below the phase LEDs on the diagnostic display panel. The green LED will turn red and the alarm will sound, if the alarm is enabled. Releasing the test button will complete the test; the red LED will turn green and the alarm will shut off.



If an inoperable condition occurs on any phase, the audible alarm sounds and the corresponding phase LED on the diagnostic display panel is illuminated red. This indicates that the device needs service by qualified electrical personnel. The audible alarm can be silenced, until a qualified person is able to evaluate and service the SPD, by pressing the alarm enable/disable button. The alarm will silence and the green alarm LED will not be lit. The red phase LED will continue to be illuminated until the inoperative condition had been cleared.

On an MA module (see Figure 8), if either LED is not lit, the module should be replaced. If both green LEDs are not lit and the diagnostic display panel has power, then power has been lost to that phase or the module should be replaced (refer to Table 2 on page 7). Refer to the final equipment instruction bulletin for MA module disconnection and access instructions.

When power is applied to the SPD and one or more of the diagnostic display panel LEDs are red, and one or more MA module LEDs are out, the appropriate MA module should be replaced. Refer to “Maintenance and Troubleshooting” on page 21 for proper troubleshooting procedures and Table 5 for replacement modules. If the module LEDs are green and the diagnostic display LEDs are red, please call the Surgelogic Technical Assistance Group at 1-800-577-7353.

Audible Alarm

Push the alarm enable/disable button to enable or disable the alarm (see Figure 9). If the green alarm LED is lit the alarm is enabled. If the green alarm LED is not lit the alarm is disabled.

Surge Counter

The surge counter displays the number of transient voltage surges since the counter was last reset. The counter is battery powered to retain memory in the event of a power loss to the IMA module. To reset the surge counter, remove all power and press the small switch located inside the unit on the underside of the diagnostic circuit board near the diagnostic display connectors (also refer to Figure 10). This will reset the counter to zero.

Dry Contacts

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Use 600 V ac rated dry contact wiring.
- Dry contact wiring must have less than 1/16 in. (1.6 mm) exposed wire from the dry contact block.
- Maintain at least 1.0 in. (25 mm) separation between dry contact wiring and the power wiring in the enclosure.

Failure to follow these instructions will result in death or serious injury.

The IMA series SPD is provided with dry contacts. The connection for the dry contacts is located on the back of the diagnostic display panel, (lower right corner, refer to Figure 10), and will accept 22 AWG (0.33 mm^2) to 14 AWG (2.1 mm^2) stranded or solid wire. The dry contacts are three-position, Form “C” type with Normally Open, Normally Closed, and Common connections.

In the unpowered state the contact is closed between terminals NC and COM. This is also the alarm condition. The opposite state, closed between terminals NO and COM, indicates that power is on to the unit and that no alarm condition exists (See Table 6).

These contacts can be used for remote indication of the SPD’s operating status to a computer interface board or emergency management system. Also, these contacts are designed to work with the SPD remote monitor option described in the next section.

Figure 9: Three-Phase Diagnostic Display Panel with Surge Counter

Note: Phase B is not present on single-phase applications.

Figure 10: Rear of Diagnostic Circuit Board

Care must be taken when installing the dry contact wiring because the terminals are on a moving door. Avoid the door hinge, any switches, and the high voltage areas of the enclosure when routing the wiring. To avoid the door hinge, tie wrap any dry contact wiring to the existing cable harness which crosses the hinge. Once the dry contact wiring is secured on a non-moving point of the enclosure, it is the user's responsibility to maintain at least 1.0 in. (25 mm) separation between 600 V ac rated dry contact wiring and the power wiring in the enclosure.

The dry contacts are designed for a maximum voltage of 24 V dc / 24 V ac and a maximum current of 2 A. Higher energy applications may require additional relay implementation outside the SPD. Damage to the SPD relay caused by use with energy levels in excess of those discussed in this instruction bulletin are not covered by warranty. For application questions, contact the Surgelogic Technical Assistance Group at 1-800-577-7353.

Remote Monitor Option

The remote monitor option has two LEDs, one red and one green, and an audible alarm with an enable/disable switch. Normal status is a lit green LED, and no audible alarm. To test the integrity of the remote monitor, press the push-to-test switch. If the alarm is enabled, the green LED will turn off, the red LED will turn on, and the alarm will sound. Releasing the switch will complete the test; the red LED will turn off, the green LED will turn on and the alarm will shut off.

If suppression on any phase is lost, the green LED will turn off, the red LED will turn on and an alarm will sound. The audible alarm can be silenced by pushing the alarm enable/disable button. The alarm will silence and the green alarm LED will not be lit. The red LED will continue to be illuminated until the inoperative condition has been cleared.

The remote monitor includes a 120 V ac to 12 V dc adapter with a six-foot power cord. Connections are made to the SPD diagnostic panel with Form “C”, three-position dry contacts (provided) and the appropriate length of solid or stranded 22 AWG (0.33 mm^2) to 14 AWG (2.1 mm^2) not provided.

Maintenance and Troubleshooting

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

Preventative Maintenance

Inspect the SPD periodically to maintain reliable system performance and continued transient voltage surge suppression. Periodically check the state of the diagnostic display panel LED status indicators. Routinely use the built-in diagnostics to inspect for inoperative modules.

FCC Part 15 notice

This equipment has been tested and found to comply with the limits for a Class B digital device, pursuant to Part 15 of the FCC rules. These limits are designed to provide reasonable protection against harmful interference in a residential installation. This equipment generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with the instructions, may cause harmful interference to radio communications. However, there is no guarantee that interference will not occur in a particular installation. If this equipment does cause harmful interference to radio or television reception, which can be determined by turning the equipment off and on, the user is encouraged to try to correct the interference by one or more of the following measures:

- Reorient or relocate the receiving antenna.
- Increase the separation between the equipment and receiver.
- Connect the equipment to an outlet on a circuit different from that of the receiver.
- Consult the dealer or an experienced radio/TV technician for help.

The user is cautioned that any changes or modifications not expressly approved by Schneider Electric could void the user's authority to operate the equipment.

About this manual

This manual discusses features of the PowerLogic™ PM8000 series power meter and provides installation and configuration instructions. Throughout the manual, the term “meter” refers to all models of the PM8000. All differences between the models, such as a feature specific to one model, are indicated with the appropriate model number or description.

This manual assumes you have an understanding of power metering and are familiar with the equipment and power system in which your meter is installed.

Topics not covered by this manual

This manual does not provide configuration information for advanced features where an expert user would perform advanced configuration. It also does not include instructions on how to incorporate meter data or perform meter configuration using energy management systems or software, other than ION Setup. ION Setup is a free configuration tool available for download from www.schneider-electric.com.

Please contact your local Schneider Electric representative to learn what additional training opportunities are available regarding ION meters.

Chapter 1 Safety precautions

Installation, wiring, testing and service must be performed in accordance with all local and national electrical codes.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E in the USA, CSA Z462 or applicable local standards.
- Turn off all power supplying this device and the equipment in which it is installed before working on the device or equipment.
- Always use a properly rated voltage sensing device to confirm that all power is off.
- Do not exceed the device's ratings for maximum limits.
- Never short the secondary of a voltage transformer (VT).
- Never open circuit a current transformer (CT).
- Always use grounded external CTs for current inputs.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

⚠ WARNING

UNINTENDED OPERATION

Do not use this device for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

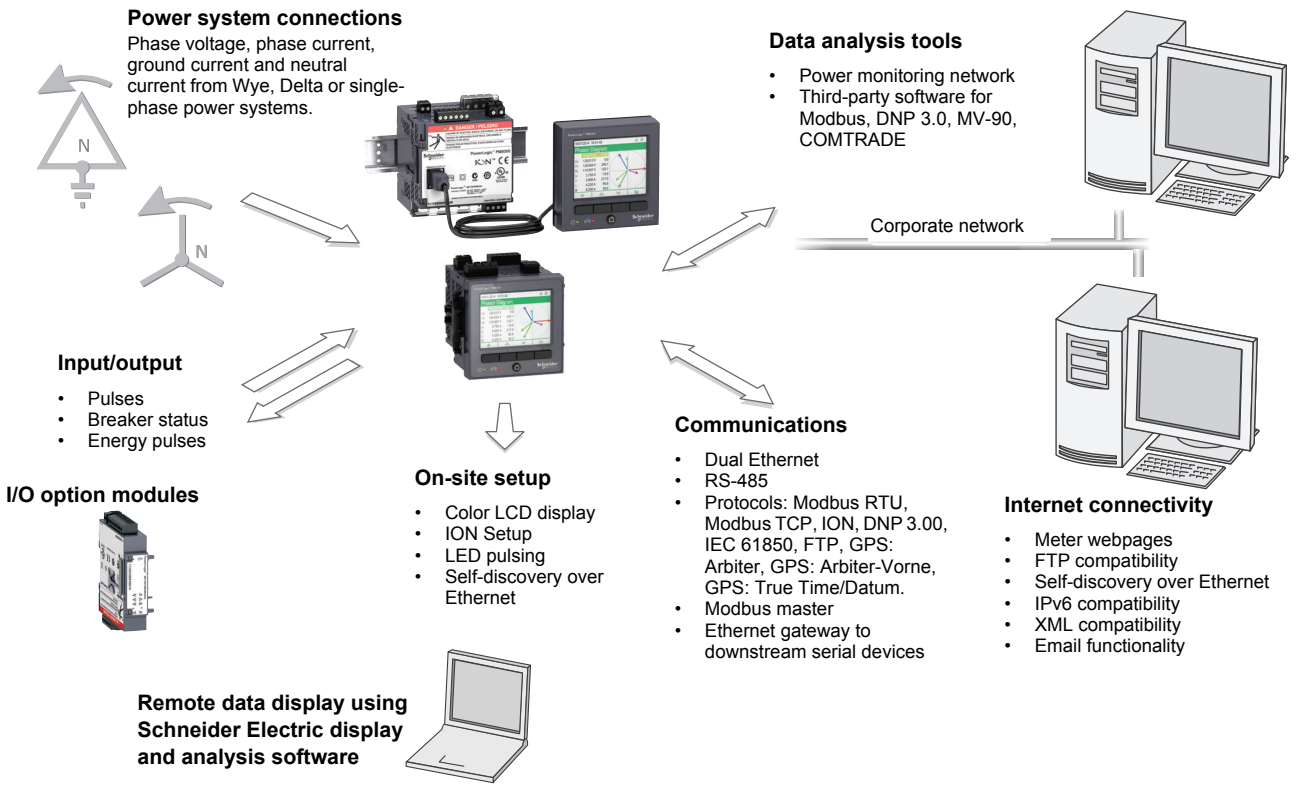
Failure to follow these instructions can result in death, serious injury or equipment damage.

Chapter 2 Introduction

PM8000 overview

The PowerLogic™ PM8000 series power and energy meters help meet the needs of your energy monitoring and cost management applications. All PM8000 meters comply to international metering accuracy standards. You can customize your meter by loading specialized frameworks, and adding option modules and incorporating mounting accessories into the physical installation.

Meter features



Feature
True RMS metering to the 63rd harmonic
Active (kW), reactive (kVAR) and apparent (kVA) power
600 V direct connection on voltage inputs
Minimum/maximum readings of metered data
Power quality readings (THD)
Downloadable firmware and template
Configuration through integrated or remote display
Modbus master, Ethernet gateway protocols supported
Web interface
Sag/Swell capture for voltage and currents
Time synchronization to 1 ms accuracy
Dual port Ethernet (two physical ports, one Ethernet IP address)
WAGES support
Time of use support
Trending and forecasting
Alarms (active and historic) display viewing and acknowledgment
Multiple languages supported

Your meter in an energy management system

In an energy management system the PM8000 meter collects and aggregates data. This data is used to perform non-critical control or shared with other equipment in the energy management system. Data from the meter can be used by energy management software to help with energy cost management, trending and forecasting, network management, power quality analysis, and more.

The meter is user-configurable to adapt to many situations. Communications allow data to be shared simultaneously across multiple networks, built-in and optional I/O provides monitoring and non-critical control capabilities, and a variety of display and analysis tools can be used to monitor your system.

The following graphic outlines your meter's capabilities in an energy management system.

Measured parameters

Your meter provides bi-directional 4-quadrant energy metering. The following is a selection of some of the values provided by your meter.

Energy

Your meter provides active, reactive and apparent energy values, including:

- kWh, kVARh, kVAh delivered and received
- kWh, kVARh, kVAh net (delivered - received)
- kWh, kVARh, kVAh total (delivered + received)
- Volt-squared-hours and amp-squared-hours

Energy parameters can be logged automatically on a programmed schedule.

All energy values represent the total for all three phases.

Demand

Your meter supports several demand calculation methods, including block, rolling block, synchronized and predicted demand. It can measure demand on any instantaneous value and record peak (maximum) and minimum demand with time and date information. Demand measurements include:

- kW, kVAR, kVA demand
- kW, kVAR, kVA peak demand
- Amps, Volts demand

Instantaneous

Your meter provides one second and half-cycle measurements, per phase and totals for many values, including:

- Voltage and current
- Apparent power (kVA), active power (kW) and reactive power (kVAR)
- Power factor and frequency
- Voltage and current unbalance

Harmonics

Your meter provides harmonic distortion metering, recording and real-time values for all voltage and current inputs, including:

- Individual harmonics (including magnitude and phase angle) up to the 63rd harmonic
- Total even harmonic distortion (TEHD) and total odd harmonic distortion (TOHD)
- Total harmonic distortion (THD) or total demand distortion (TDD)
- K-factor, Crest factor

Min/max recording

Your meter records new minimum and maximum data every recording interval for the following vlaues:

- Voltage and current
- kW, kVAR and kVA
- Power factor
- Frequency
- Voltage unbalance
- Plus any measured value

Power quality

Your meter measures and records voltage and current sags and swells. Your meter also has many power quality related features, including:

- Disturbance direction detection: this allows the meter to analyze disturbance (sag/swell) information to help determine the direction of the disturbance relative to the meter.
- Setpoint learning: this allows the meter to learn the power quality characteristics of your system, to help identify what constitutes a sag or a swell.
- COMTRADE: this allows the meter to save waveform data in COMmon format for TRAnsient Data Exchange (COMTRADE) on its internal FTP server.

Your meter includes the following power quality compliance:

- EN50160: Your meter measures and presents statistics for determining EN50160 compliance.
- IEC 61000-4-30: Your meter complies with the IEC 61000-4-30 power quality standard.
- IEC 62586-1: Your meter complies with the IEC 62586-1 power quality standard.

Localization options

The meter can be customized to use different regional settings, including:

- The language used for the display and webpages
- Time, date and digit formats
- IEC/IEEE symbols and calculations

Data display and analysis tools

Software

Your meter integrates with display and analysis software available from Schneider Electric™, such asStruxureWare™ Power Monitoring Expert that lets you analyze and monitor your system and produce reports for different departments in your organization. This software is designed to make use of your meter's advanced capabilities. You can also use the data acquired by the meter in a variety of third-party systems.

Display

Use the meter's display for local monitoring and standalone applications. The color LCD display lets you view real-time values, events and alarms, and perform basic device configuration. Connect a remote display to a meter without an integrated display to get the same functions as those provided on the integrated display.

Active and historical alarms

The meter's display shows an alarm icon and the alarm LED flashes if your meter detects an active alarm condition. Depending on the priority of the alarm, your meter's display also flashes. You can view and acknowledge active alarms and historic alarms and events through the display and software webpages. An active alarm becomes a historic alarm when the alarm condition no longer exists.

Meter internal web server feature

Your meter's internal web server provides quick and easy access to real-time energy and basic power quality information without special software using an on-board web server combined with an Ethernet port. The built-in web pages display selected energy and power quality information through the web-enabled device; these pages also support basic meter configuration.

Email messaging feature

You can configure your meter to automatically email information, whether notification of a high-priority event or a regularly scheduled send of logged data, to an external email address. Specify the type of event that triggers an email alert, such as a power quality disturbances or interval for logged data. Email messages from your meter are received like any other email message.

Supported protocols

Your meter's fundamental protocol and architecture is ION. You can integrate the meter into various industry-standard networks. Data that the meter measures can be made available to other devices using Modbus, DNP 3.0 and SNMP as well as the MV-90 translation system. You can configure the meter to import data from other devices on

these networks. Your meter supports the IEC 61850 protocol and COMTRADE waveform data format.

Your meter also supports IPv6, DPWS and RSTP Ethernet protocols.

ION Setup device configuration tool

ION Setup is a free configuration tool for your meter that allows you to remotely configure your meter's features over Ethernet or serial communications.

- Use the Setup Assistant to guide you through the process of configuring your meter.
- Use the real-time data screens to verify your meter's configuration.
- Use the data screens to view your meter's recorded data.
- Use the charting function to view your meter's recorded waveforms.

You can download ION Setup from www.schneider-electric.com.

NOTE: Advanced users with a thorough understanding of their meter's architecture, protocols, and the power system in which their meter is installed, can use the advanced mode of ION Setup to create specialized features on their meter.

- See the online ION Setup help, available from www.schneider-electric.com, for instructions on connecting to your meter and accessing the Setup Assistant.

Additional information and files

The most up-to-date documentation about your meter is available for download from www.schneider-electric.com. You can also contact your local Schneider Electric representative for more information.

Installation sheets

Multilingual installation sheets are shipped with each device or accessory, and provide the information required to install the product.

ION reference

The ION reference describes ION architecture (the common software architecture in all ION devices) and provides an explanation of each of the ION modules.

ION device template reference

The ION device template reference details the type and quantity of ION modules available on your device and how they are configured in the default template.

ION Setup

ION Setup is a free meter configuration tool that can be downloaded for free at www.schneider-electric.com. It has online help that provides instructions on how to connect to and configure your meter using ION Setup.

Technical notes

Technical notes provide instructions for using meter features and for creating custom configurations.

Protocol documents

Each protocol document contains information explaining how your meter interacts with a protocol, such as DNP 3.0, IEC 61850 and MV-90.

Additional files

Additional files for your meter are available for download from www.schneider-electric.com.

File type	Description
Firmware (*.upg)	Firmware upgrade files let you upgrade your meter's firmware to get new features.
Template (*.dcf)	Template files let you replace your meter's existing template with an updated template with new features.
Protocol files	Files required to support a particular protocol on your meter, such as the MIB file for SNMP and your meter's Modbus register map.
Remote display (*.bin) and option module (*.si9) firmware	Firmware upgrade files let you upgrade your remote display or option module's firmware.

Display and analysis software

Documentation for display and analysis software available from Schneider Electric, such as StruxureWare Power Monitoring Expert, is available for download from www.schneider-electric.com.

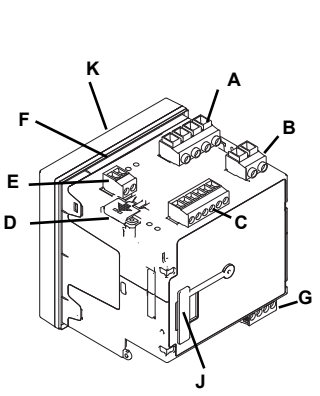
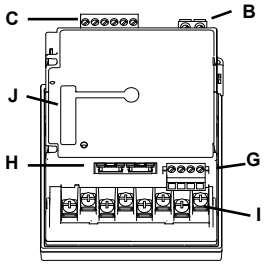
Meter types



The PM8000 series is available in two physical form factors, and has several accessories:



Model	Commercial reference	Description
PM8240	METSEPM8240	Panel-mounted meter with integrated display
PM8243	METSEPM8243	DIN rail-mounted meter without display, which can be connected to a remote display
PM8244	METSEPM8244	DIN rail-mounted meter packaged with a remote display
PM89RD96	METSEPM89RD96	Remote display (for DIN meter only)
PM89M2600	METSEPM89M2600	Digital I/O option module (2 out, 6 in)
PM89M0024	METSEPM89M0024	Analog I/O option module (2 out, 4 in))
PM8000SK	METSEPM8000SK	PM8000 voltage and current sealing kit
METSEPMAK	METSEPMAK	PM8000 mounting adapter kit for remote display and DIN meter

Mounting adaptors

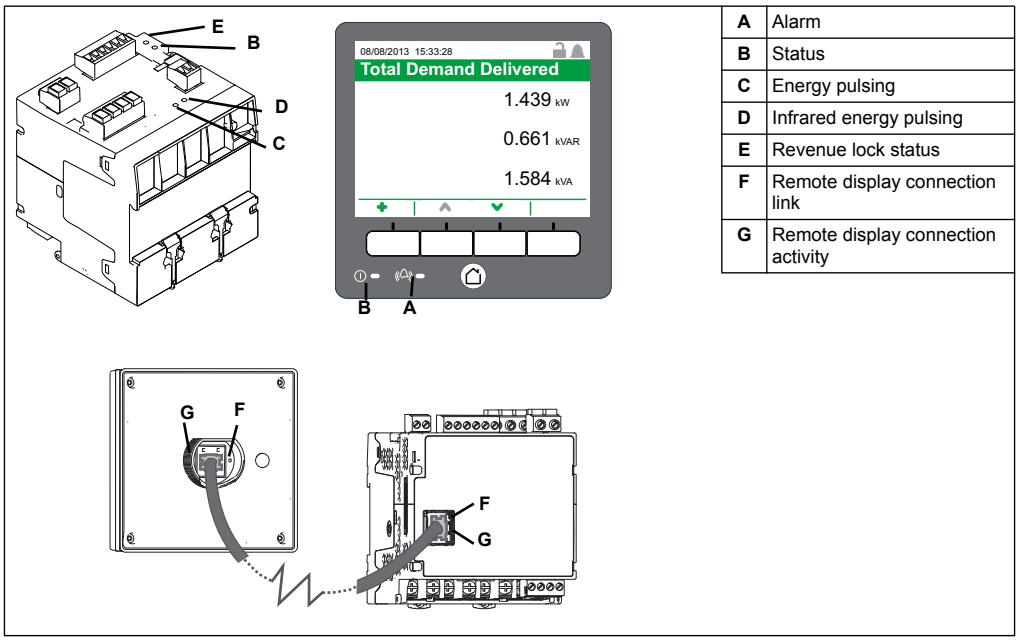
There are different mounting adaptor accessories that can help when installing your meter in existing panels and cutouts where the default mounting hardware is not appropriate. Mounting adaptor kits are ordered separately from the meter.

Related topics

- See the PM8000 catalog pages, available from www.schneider-electric.com, or consult your local Schneider Electric representative for information about mounting adaptors available for your meter.

Other accessories

Voltage and current input covers



Sealable voltage and current input covers are available and can be ordered separately for your meter. These covers are included for meter models where sealable voltage and current covers are required to comply with revenue or regulatory standards.

Replacement hardware

You can order replacement mounting and installation hardware for your meter and accessories.

Energy pulsing LED behavior

The visible and infrared LEDs are configured by default to pulse based on the energy (kWh) received by the meter. You can configure the pulse weight (pulses per kWh) and the energy source.

Energy pulsing is used to help verify the energy measurement accuracy of your meter for revenue purposes.

Related topics

Revenue lock LED behavior

State	Description
Off	The meter is not revenue locked.
On	The meter is revenue locked.
Flashing	New revenue lock state is pending; power cycle your meter to set the revenue lock to on or off.

Remote display connector LED behavior

There are two LEDs in the remote display connector.

LED	Description
Green (link)	On: link established. Off: no link established with the remote display. Check the connections to the remote display and DIN meter.
Yellow (activity)	Flashing: active communications between the meter and the remote display. Off: no communication activity. Check remote display and meter operation.

Chapter 4 Mounting and installation

This section provides supplemental information to help mount and install your meter. It is intended to be used in conjunction with the installation sheet that ships in the box with your meter and accessories. See your device's installation sheet for information related to installation, such as dimensions, mounting and wiring instructions.

The latest technical documentation related to your meter and accessories is available for download from www.schneider-electric.com.

Before you begin

Carefully read and follow the safety precautions and instructions in the installation sheet before working with your meter or accessory.

Safety precautions

Installation, wiring, testing and service must be performed in accordance with all local and national electrical codes.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E in the USA, CSA Z462 or applicable local standards.
- Turn off all power supplying this device and the equipment in which it is installed before working on the device or equipment.
- Always use a properly rated voltage sensing device to confirm that all power is off.
- Do not exceed the device's ratings for maximum limits.
- Do not use this device for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.
- Never short the secondary of a voltage transformer (VT).
- Never open circuit a current transformer (CT).
- Always use grounded external CTs for current inputs.

Failure to follow these instructions will result in death or serious injury.

1. Turn off all power supplying this device and the equipment in which it is installed before working on the device or equipment.
2. Always use a properly rated voltage sensing device to confirm that all power is off.

Mounting

Panel mount meters

The meter retainer clips, located on either side of the meter base and used to secure the meter in the panel, do not usually require any tools to install. If necessary, for panels with limited space, you can use a long-handled slot screwdriver to help install the meter retainer clips.

Mounting adaptors

There are different mounting adaptor accessories that can help when installing your meter in existing panels and cutouts where the default mounting hardware is not appropriate. Mounting adaptors are ordered separately from the meter.

Related topics

- See the PM8000 catalog pages, available from www.schneider-electric.com, or consult your local Schneider Electric representative for information about your device, its options and accessories.

Wiring

This information is supplemental to the installation sheets that shipped with your meter or accessory.

Remote display mounting and wiring

- The remote display can only be used with the DIN meter; it cannot be used by meters with an integrated display.
- The remote display's power and communications is provided through a single, direct, point-to-point connection from the remote display to the DIN meter.

Meter wiring

Power system wiring

You can connect the meter's voltage inputs directly to the phase voltage lines of the power system if the power system's line-to-line or line-to-neutral voltages do not exceed the meter's direct connect maximum voltage limits. The maximum voltage allowed for direct connection may be lower than the manufacturer-specified limits, depending on the local electrical codes and regulations.

If your system voltage is greater than the specified direct connect maximum voltage, you must use PTs (potential transformers) to step down the voltages.

Serial communications (RS-485) wiring

Devices connected to the bus, including the meter, converter(s) and other hardware, must be wired as follows:

- Connect the shield of each segment of the cable to ground at one end only.
- Isolate cables as much as possible from sources of electrical noise.
- Use an intermediate terminal strip to connect each device to the bus. This allows for easy removal of a device for servicing if necessary.
- Install a ¼ Watt termination resistor between the positive and negative terminals of the device at each end of a straight-line bus. The resistor should match the nominal impedance of the RS-485 cable. Consult the cable manufacturer for the cable impedance value.
- Turn on RS-485 biasing if your meter is the RS-485 master device.
- Avoid device connections that cause a branch or "Tee" in the main RS-485 bus as they can lead to signal reflections that may result in interference.
- Do not connect more that two cables at any connection point on the RS-485 bus.

RS-485 terminals

+	Data plus. This transmits/receives the non-inverting data signals.
-	Data minus. This transmits/receives the inverting data signals.
⏚	Shield. Connect the bare wire to this terminal to help suppress signal noise that may be present. Ground the shield wiring at one end only (either at the master or the last slave device, but not both).
C	Signal common. This provides the voltage reference (zero volts) for the RS-485 signals.

NOTE: If some devices in your RS-485 network do not have the common (C) terminal, use the bare wire in the RS-485 cable to connect the common terminal from the meter to the shield terminal on the devices that do not have the common terminal.

Ethernet communications

Your meter's dual port Ethernet connections enable you to use straight-line or network loop (ring) topologies. If local network loop Ethernet topologies are required, you must enable RSTP for your meter's Ethernet communications to function.

Only use unshielded CAT5/5e UTP Ethernet cables to wire your meter's Ethernet communications. Other cable types may provide an undesired ground path.

NOTICE

EQUIPMENT DAMAGE

Only use unshielded CAT5/5e UTP Ethernet cables.

Failure to follow these instructions may result in equipment damage.

Option modules

Perform an option bus reset to restart the option bus and re-initialize the option modules attached to your meter.

Related topics

- See "Option modules" on page 43 for more information about option modules.
- See "Resets" on page 153 for more information about the resets available on your meter.

Chapter 5 Display and meter setup

Your meter can have either an integrated or an optional remote display. The display allows you to view meter data and perform basic configuration. The integrated and remote display screens have the same meter data and setup screens. Only meters without an integrated display can use the remote display.

Display overview

A	Date/time
B	Revenue lock icon
C	Alarm icon
D	Display
E	Navigation icons
F	Navigation buttons
G	Home button
H	Alarm LED
I	Status LED

Home button

Pressing the home button takes you to the associated menu screen. If you are in a data screen, pressing the home button takes you to the display menu, and pressing home twice takes you to the summary display screen. If you are in a setup screen, pressing home takes you to the setup menu, and pressing home again takes you to the display menu.

Revenue lock icon

The revenue lock icon indicates the lock status of the meter. When gray and open, the meter is unlocked. When green and closed, the meter is locked. You can lock and unlock your meter using the revenue lock switch located on the body of your meter.

Alarm icon

The alarm icon indicates the highest level and state of alarms detected by your meter. For example, if the meter detects a low priority and a high priority active alarm, the alarm icon indicates a high priority active alarm.

NOTE: Alarms can only be viewed and acknowledged through your meter's display.

Icon	Description
	Active alarm indicator: • Red: high priority alarm state detected • Yellow: medium priority alarm state detected • Blue: low priority alarm state detected The alarm indicator flashes until you acknowledge the alarm. The alarm indicator changes to the historic alarm indicator of the appropriate level when the alarm state is no longer detected by the meter. **NOTE:** Your meter's display backlight flashes for unacknowledged high priority active alarms.

Icon	Description
	Unacknowledged historic alarm indicator: • Red: unacknowledged high priority historic alarm • Yellow: unacknowledged medium priority historic alarm **NOTE:** Low priority historical alarms are not indicated. The active alarm indicator changes to the historic alarm indicator of the appropriate level when the alarm state is no longer detected by the meter.
	No active or unacknowledged high or medium priority historic alarms

- See “Alarms and alerts” on page 147 for more information about your meter’s alarms.

Alarm and status LED indicators

Your meter has two LED indicators on the display. These LEDs cannot be configured for other uses.

LED	Description
Status	Off: unpowered Steady green: normal operation Flashing red: no communications (remote display only) Steady red: firmware upgrade required (remote display only) Flashing red/green: startup or firmware upgrade sequence in progress
Alarm	Off: no active or unacknowledged historic alarms On: acknowledged active alarm Flashing: active alarm **NOTE:** Your meter’s display backlight flashes for unacknowledged high priority active alarms.

- See “Indicator LEDs” on page 21 for a description of the meter’s communication and status LEDs.

Navigation symbols

Navigation symbols are displayed on the bottom of the screen above their corresponding navigation button.

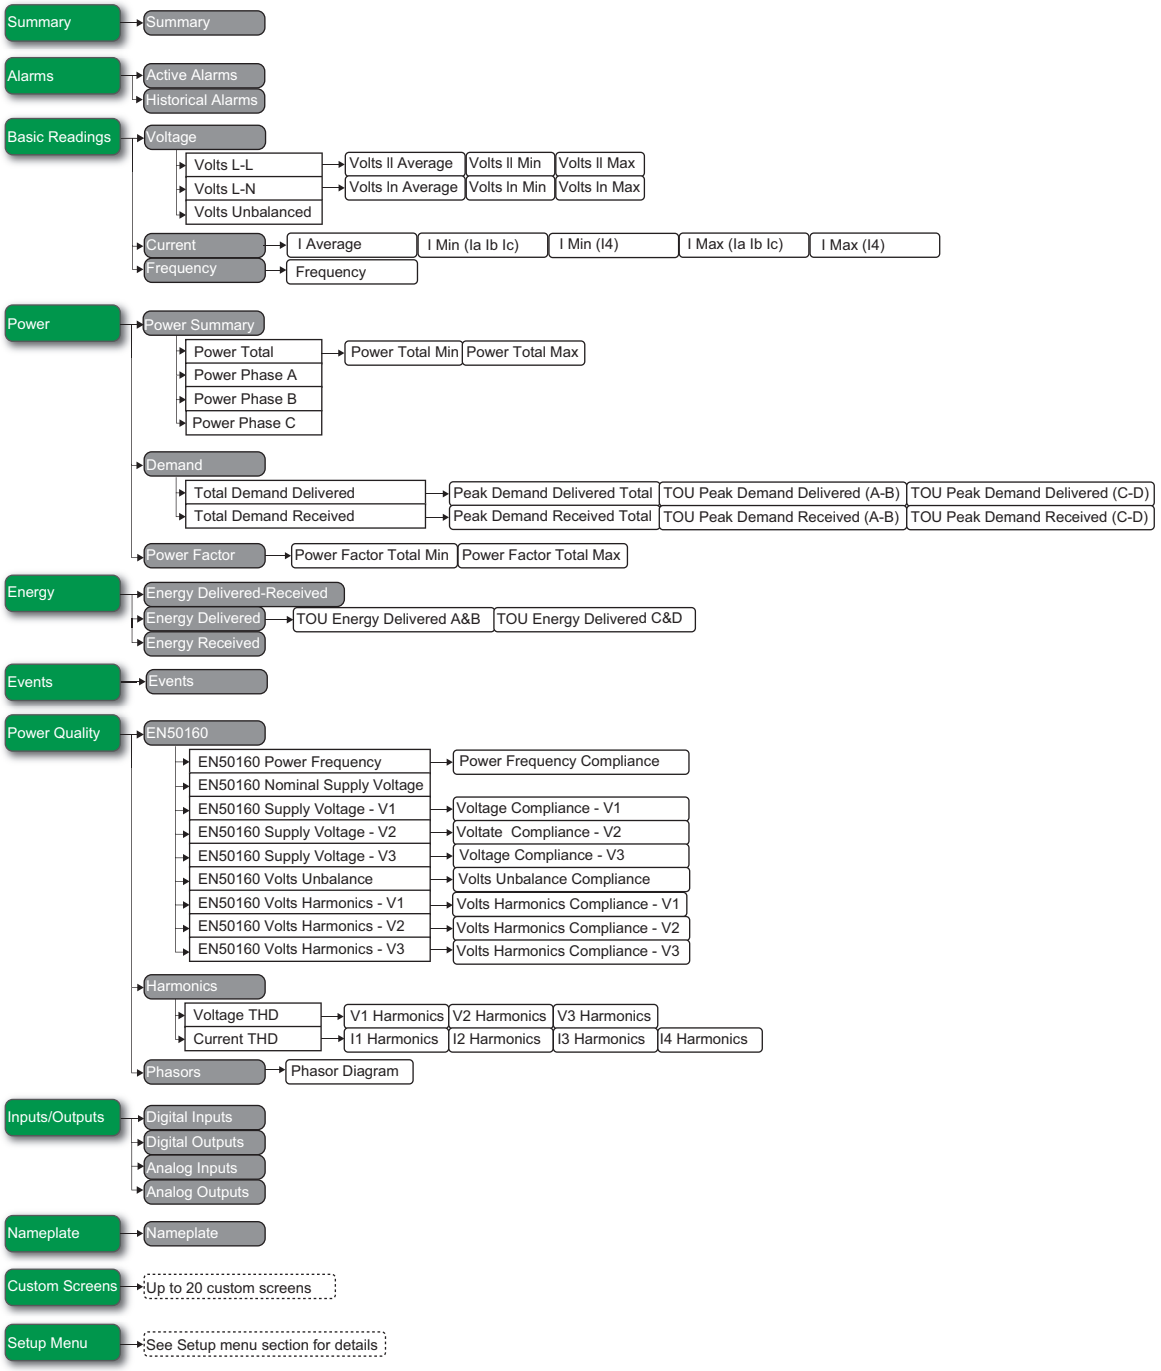
NOTE: If the symbol is gray, that navigation function is not available.

Symbol	Description
	**More** Pressing this button displays additional screens.
	**Left** Pressing this button moves the displayed cursor one position to the left. If you are in a more or info screen, it returns you to the previous screen.
	**Right** Pressing this button moves the displayed cursor one position to the right.

Symbol	Description
	**Up** Pressing this button takes you to the previous screen or menu item.
	**Down** Pressing this button takes you to the next screen or menu item.
	**Select** Pressing this button selects or confirms the highlighted value.
	**Cancel** Pressing this button cancels the current selection and returns you to the previous screen.
	**Graphic** Pressing this button takes you to a graphical data display.
	**Numeric** Pressing this button takes you to a numeric data display.
	**Info** Pressing this button takes you to a detailed information screen.
	**Edit** Pressing this button allows you to edit the displayed parameter.
	Pressing these buttons allow you to navigate parameter tables in the setup screens.
	Pressing both buttons allows you to perform the described action.

More screens access

Pressing the navigation button associated with the more icon brings up a list of additional screens related to the displayed screen. Press cancel to remove the list. If you do not press any button, the list automatically disappears after a short period of time.



Overrange indication

If any value measured by the meter is too large to fit on the meter's display, the meter initially reduces the size of the text to try and make the value fit. If the value is still too large to be displayed, the meter truncates the value starting with the least significant digit, and encloses the truncated value in a red box.

Display menu

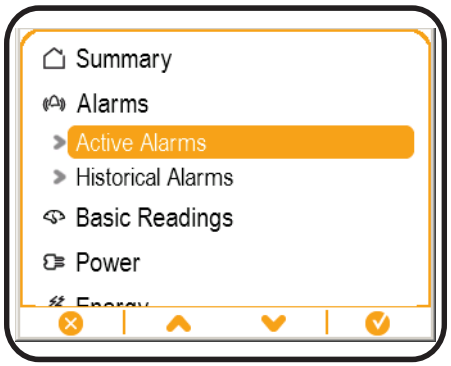
The display menu allows you to select data for viewing and to access the setup menu.

NOTE: Your meter's menus may appear slightly different than shown depending on your display settings.

Viewing data using your meter's display

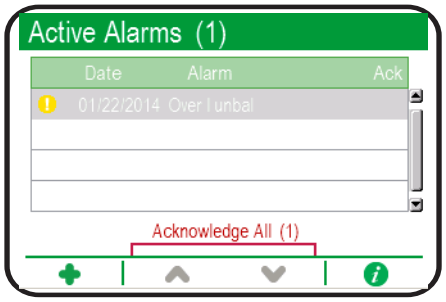
Use the navigation buttons to view data on your meter's display.

The following examples show how to use the navigation buttons to view data in numeric or graphical format, select and view additional menu screens, and view detailed information about alarms and acknowledge them.

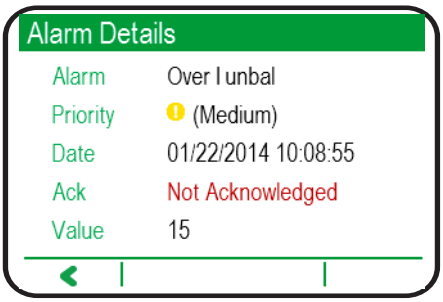


NOTE: Your display may appear differently than shown, depending on your meter's power system and display settings.

NOTE: Your navigation icons change color depending on the type of screen being viewed. If an icon is gray, that navigation option is not available and nothing will happen when you press the button associated with that icon.

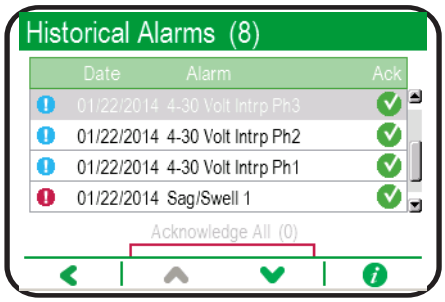


Example: viewing the alarm screens



Use the display navigation buttons to access the alarm screens, display detailed information, and acknowledge active and historic alarms.

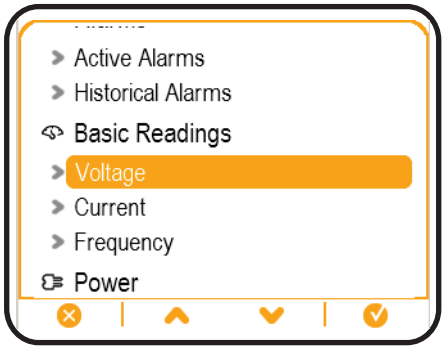
1. Press ⌂ to display the menu. Press ▲ or ▼ until **Alarms** is highlighted. Press ✓ to display the alarm screens. Press ▼ until Active Alarms is highlighted. Press ✓ to display Active Alarms.The Active Alarms title lists, in brackets, the total number of active alarms.



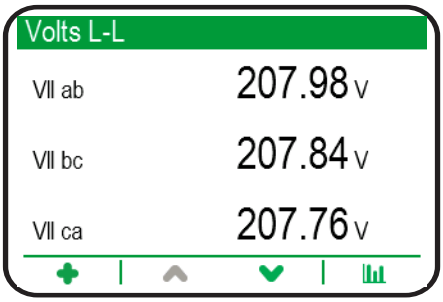
2. Press ▲ or ▼ to highlight a specific alarm, in this case an unbalanced currents alarm. Press ⓘ to display detailed information about the highlighted alarm, and press ◀ to return to the Active Alarms screen. Press both ▲ and ▼ simultaneously to acknowledge all active alarms.

3. Press ⌂ to display the menu. Press ▼ to highlight Historical Alarms. Press ✓ to display Historical alarms.The Historical Alarms title lists, in brackets, the total number of historic alarms.

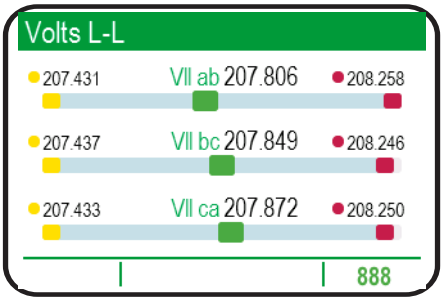
4. Press ▲ or ▼ to highlight a specific alarm, in this case a 4-30 voltage interruption alarm. Press ⓘ to display detailed information about the highlighted alarm. Press both ▲ and ▼ simultaneously to acknowledge all historical alarms.



5. Press ⌂ to return to the menu.

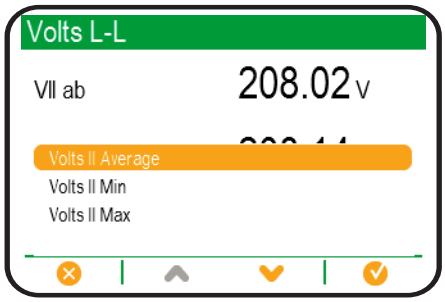


Example: viewing the voltage screens

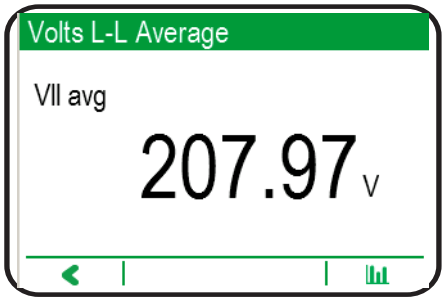


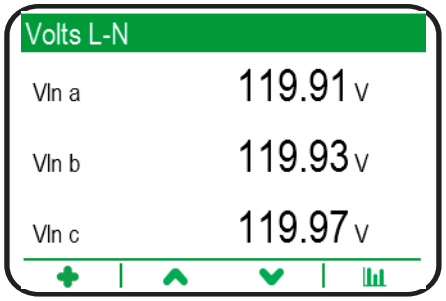
Use the display navigation buttons to view screens, display detailed information, and display graphical representations of measured voltage data.

1. Press ⌂ to display the menu. Press ▲ or ▼ until Basic Readings is highlighted. Press ✓ to view the basic readings screens. Press ▼ until Voltage is highlighted. Press ✓ to view the voltage screens.Voltage line-to-line values are displayed.

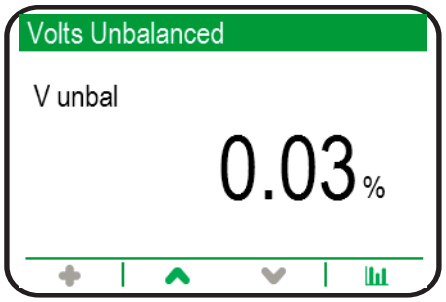


2. Press 📊 to view a graphical display of historic voltage values, then press 888 to return to the numeric display. Press ✚ to show a list of additional screens.





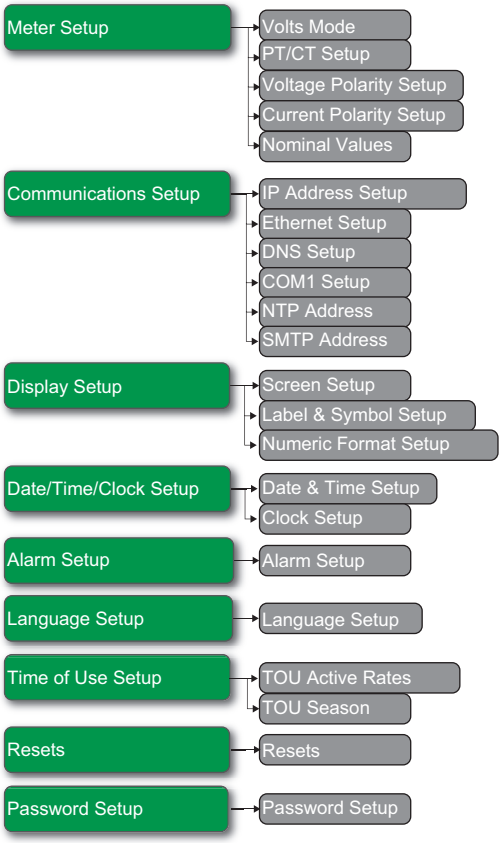
3. Press ▲ or ▼ to highlight an additional screen, in this case, Volts II Average. Press ✓ to go to the highlighted screen. Volts II Average displays the average line-to-line voltage.



4. Press to view a graphical display of average voltage values, then press 888 to return to the numeric display. Press to return to Volts L-L.

5. Press to view Volts L-N, which also has additional screens and the ability to view the information in a graphical format.

6. Press again to view Volts Unbalanced. This is the last voltage screen, so is grayed out and unavailable. Press to return to Volts L-N, and press again to return to Volts L-L.



Setup menu

Meter configuration can be performed through the display, using the meter's webpages or through software. This section contains information on how to set up the meter using the display. You must have your meter's security settings configured to allow front panel (display) programming in order to set up the meter using the display.

NOTE: Your display may appear differently than shown, depending on your meter's power system and display settings.

NOTE: Some setup parameters cannot be configured when revenue security is enabled.

Related topics

Setting up your meter using the display

Use the navigation buttons and displayed parameters to configure your meter.

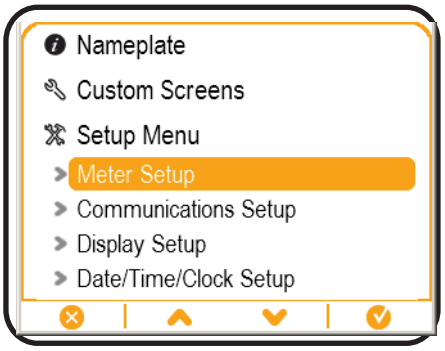
The following example shows how to use the navigation buttons to select parameters, enter numeric information or select parameter values from lists.

NOTE: Your display may appear differently than those shown, depending on your meter’s power system and display and localization settings.

NOTE: Your navigation icons change color depending on the type of screen being viewed. If an icon is gray, that navigation option is not available and nothing will happen when you press the button associated with that icon.

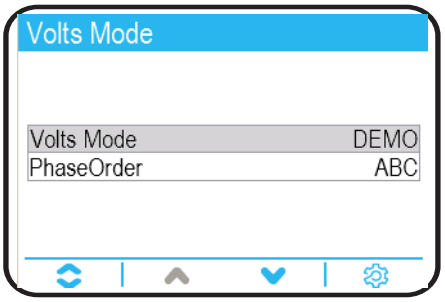
NOTE: Your meter goes back to displaying data after a period of inactivity in the setup menu screens.

NOTE: Your meter locks you out of display configuration after you have exceeded the maximum number of attempts to enter an password.



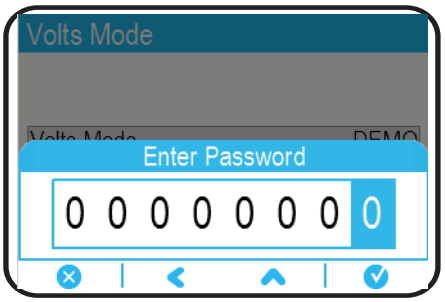
Your meter's default display password is 0 (zero).

Example: setting volts mode and PT/CT ratios

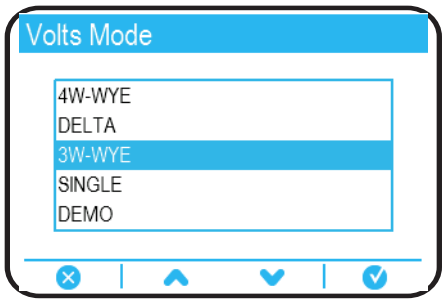


Use the display navigation buttons to set your meter's volts mode and PT ratios.

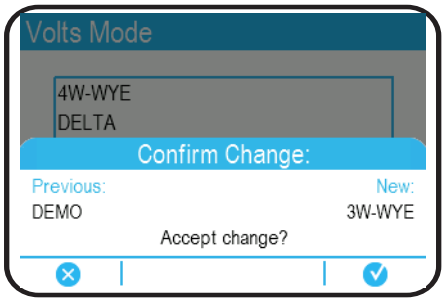
NOTE: Potential transformers (PT) are also known as voltage transformers (VT).



1. Press ⌂ to display the menu. Press ▼ until Setup Menu is highlighted. Press ✓ to display the Setup Menu.The **Setup Menu** lists the setup selections on your meter.

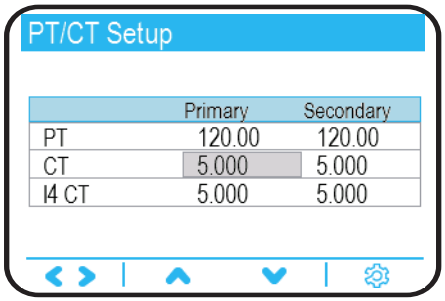


2. Press ▲ or ▼ to highlight the different setup menu selections. Highlight Meter Setup and press ✓ to select the meter setup screens.The Volts Mode setup screen is displayed.
3. Press ⇄ to highlight Volts Mode. Press ⚙ to edit the Volts Mode.The Enter Password screen is displayed.



4. Press ▲ to change the value of the highlighted digit (0 - 9). Press ◀ to go to the next digit. Press ✓ to enter your password.The volts mode configuration screen is displayed.

5. Press ▲ or ▼ to highlight the desired volts mode from the list, in this case, 3W-WYE. Press ✓ to select the highlighted volts mode. A confirmation screen is displayed, showing your meter's previous setting and newly selected setting.



6. Press ✓ to confirm, and the new setting is applied to your meter. Press ✗ to cancel and maintain your meter's original setting.

7. In the Volts Mode screen, press ▼ to go to the PT/CT Setup screen.
8. In the PT/CT Setup screen, press ◄ ► to highlight the potential transformer (PT) or current transformer (CT) value for editing. Press ⚙ to edit the highlighted value.

   NOTE: If you have exceeded the password timeout period, you are prompted to enter your meter's display password.

9. Press ▲ to change the value of the highlighted digit (0 - 9). Press ◄ to go to the next digit. Press ✓ to enter the new value. When the confirmation screen is displayed, press ✓ to confirm the new value or ✗ to revert to the original value.

Minimum configuration requirements for basic metering

At a minimum, you must configure the following parameters to help your meter perform basic metering functions.

Setup screen	Screen	Minimum configuration
Meter Setup	Volts Mode	Volts Mode
	PT/CT Setup	PT, CT and I4 CT Primary and Secondary
	Nominal values	V nominal, I nominal, Nominal Frequency

NOTE: You must also configure all the parameters related to the meter features you are using, for example, you must configure the DNS server address if you are using the meter’s DNS feature.

Setup parameters

The following sections list the parameters that can be configured using your meter’s display.

NOTE: Some parameters may appear differently than shown, depending on your meter’s power system and display settings.

Meter setup

Screen title	Parameter	Values	Description
Volts Mode	Volts Mode	4W-Wye, Delta, 3W-Wye, Single, Demo	The power system’s configuration
	PhaseOrder	ABC, ACB	The power system’s phase order
PT/CT Setup	PT Primary	1 to 999,999.99	The potential transformer’s primary winding voltage rating **NOTE:** PTs are also referred to as a VTs or voltage transformers.
	PT Secondary	1 to 999,999.99	The potential transformer’s secondary winding voltage rating **NOTE:** PTs are also referred to as a VTs or voltage transformers.
	CT Primary	1 to 999,999.99	The current transformer’s primary winding current rating
	CT Secondary	1 to 999,999.99	The current transformer’s secondary winding current rating.
	I4 Primary	1 to 999,999.99	The I4 current transformer’s primary winding current rating
	I4 Secondary	1 to 999,999.99	The I4 current transformer’s secondary winding current rating
Voltage Polarity Setup	Va Polarity	Normal, Inverted	The polarity of the potential transformer on Va

	Nominal Frequency	50, 60	The nominal (normal) frequency of the power system

Communications Setup

Screen title	Parameter	Values	Description
IP Address Setup	IP Address	As defined by your network's system administrator	Sets the IP address for the meter **NOTE:** Your meter's default IP address is 169.254.0.10
	SubnetMask		Used if subnetting applies to your network
	Gateway		Used in networks with multiple segments
	MAC Address	Not configurable	Your meter's media access control (MAC) address.
Ethernet Setup	Enable RSTP	Yes, No	Specifies if rapid spanning tree protocol (RSTP) is enabled **NOTE:** If local network loop or ring Ethernet topologies are required, you must enable RSTP for your meter's Ethernet communications to function
	Enable ION Over TCP	Yes, No	Specifies if ION protocol communications are enabled over Ethernet
	Enable Web Server	Yes, No	Specifies if the meter's internal web server is enabled
DNS Setup	Primary DNS	As defined by your network's system administrator	Sets the address for the primary DNS server that is configured to resolve domain names
	Secondary DNS		Sets the address for the secondary DNS server that is configured to resolve domain names
COM1 Setup	Protocol	ION, Modbus RTU, Modbus Master, DNP v3.00, EtherGate, GPS: Truetime/Datum, GPS: Arbiter, GPS: Arbiter-Vorne, Factory	Sets the communications protocol for your meter's RS-485 port
	Baud Rate	2400, 4800, 9600, 19200, 38400, 57600, 115200	Sets the data rate, in bits per second
	RTS Delay	0 to 1	Sets the transmit delay in seconds
	Unit ID	1 to 9999	Sets the meter's unique ID on the RS-485 network **NOTE:** Modbus serial device range 0 to 247
	Serial Port	8N1, 8N2, 8E1, 8E2, 8O1, 8O2	Sets the parity and stop bits for the port
	RS485 Bias	Off, On	Turns on biasing when mastering devices over the RS-485 port
NTP Address	NTP Server	As defined by your network's system administrator	Specifies the IP address of the SNTP or NTP server used by the meter for time synchronization
SMTP Address	SMTP Server	As defined by your network's system administrator	Specifies the IP address of the SMTP server used by the meter for sending email

Display Setup

Screen title	Parameter	Values	Description
Screen Setup	Backlight Timeout	0 to 720	Specifies how many seconds the display's backlight remains lit after the last button press
Label & Symbol Setup	Phase Lbls	ABC, 123	Sets the voltage and current phase labels
	Measurement Symbols	IEEE, IEC	Specifies whether IEEE or IEC measurement symbols are applied to displayed values
	PF Convention	IEEE, IEC	Specifies whether IEEE or IEC power factor conventions are applied to displayed values
Numeric Format Setup	Digit Grouping	1000.0, 1,000.0, 1 000,0	Specifies how digits are grouped for display
	Volts Resolution	1., 1.X, 1.XXX, 1.XXXX	Specifies the number of decimal places displayed for voltages
	Current Resolution	1., 1.X, 1.XXX, 1.XXXX	Specifies the number of decimal places displayed for currents
	Power Resolution	1., 1.X, 1.XXX, 1.XXXX	Specifies the number of decimal places displayed for power and energy measurements

Alarm Setup

⚠ WARNING

UNINTENDED OPERATION

Do not use this device for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

You can disable alarms through the display in order to prevent nuisance alarms:

Screen title	Parameter	Description

	Current Swell Ph2	Current swell alarms for phase 2
	Current Swell Ph3	Current swell alarms for phase 3

[1] Any Setpoint or Relative Setpoint module with an event priority greater than the low alarm event priority is also displayed on this screen.

You can only enable or disable alarms using the display. Alarm configuration is done using ION Setup. Alarms with a priority less than low (info only or none) are not displayed.

You must configure all the parameters related to the alarm for alarm functions to operate. For example, for the Over Ia alarm to operate, you must enter the nominal value and the conditions that define an alarm state, even if the alarm is shown as Enabled on the Alarm Setup screen.

Language Setup

Select the language to be shown on the meter's display. By default, your meter has the following languages:

- English
- Spanish
- French
- German
- Italian
- Portuguese
- Russian
- Chinese (simplified)

Resets

NOTICE

LOST DATA

Save your meter's data before performing a reset.

Failure to follow these instructions can result in data loss.

The following resets can be performed using the display:

Screen title	Parameter	Description
Resets	Master Reset	• Clears all the cumulative and derived quantities from the meter (including demand, peak demand, energy, revenue and test mode parameters) • Clears meter event and waveform logs • Clears COMTRADE waveform records from the meter's internal FTP server • Clears the meter's data logs
	Peak Demand Reset	Clears the peak demand values logged in the meter
	Min/Max Reset	Clears all accumulated maximum and minimum values stored in the meter
	Digital Input Count Reset	Clears the digital input state change counters
	Harmonics Min/Max Reset	Clears all accumulated maximum and minimum harmonics values stored in the meter
	Disturbance Count Reset	Clears the sag/swell event counter
	EN50160 Reset	Clears all EN50160 parameters and statistics accumulated in the meter
	Option Modules Reset	Restarts all option modules attached to the meter

Password Setup

It is strongly recommended that you change your meter's display (front panel) password from the default value of 0 (zero).

If your meter's user access information is lost, you must return the meter to the factory, where your meter is reset to its factory defaults and all logged data is lost.

NOTICE

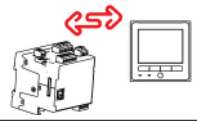
DATA LOSS

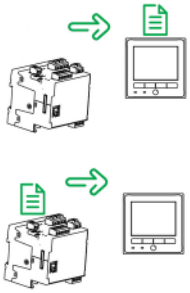
Record your device's user and password information in a secure location

Failure to follow these instructions may result in data loss.

Screen title	Parameter	Values	Description
Password Setup	Password	0 to 99999999	Sets the password that must be entered in order to configure parameters using the meter's display **NOTE:** This is also the password used to access the meter's webpages when standard security is enabled

Display behavior





Display backlight

Your meter's display backlight dims after a defined period of inactivity.

When the meter detects an unacknowledged active high priority alarm, the display flashes until the alarm is acknowledged.

Remote display troubleshooting icons

Your meter's remote display shows the following troubleshooting icons in addition to the meter's status LED information:

Icon	Description
	Your remote display cannot communicate to your meter. Check the connection between your meter and the display. Check the meter's status LED to confirm that the meter is operating normally.
	Your remote display needs updated firmware for compatibility with your meter.
	Your remote display is undergoing a firmware upgrade. Do not disconnect your remote display from your meter.

- See “Loading remote display firmware using FTP” on page 80 for instructions on how to load remote display firmware.

Localization

The localization settings on the meter affect how information is displayed as well as how some values are calculated. Options include language, number formats as well as the IEEE (Institute of Electrical and Electronics Engineers) or IEC (International Electrotechnical Commission) conventions used for power, power factor and energy.

You can configure your meter’s localization settings using ION Setup.

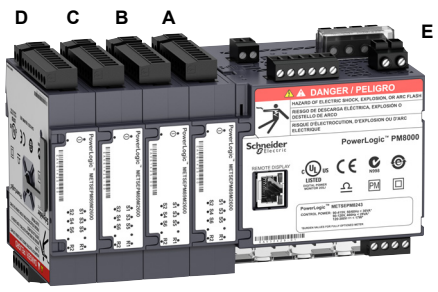
Lost user access

If you lose your meter’s user access information, contact your local Schneider Electric representative for instructions on how to return your meter for factory reconfiguration.

NOTE: Have your meter’s serial number available for reference.

Chapter 6 Option modules

This section supplements the option module installation sheets and provides additional information regarding physical characteristics and capabilities.



Related topics

- See your device's installation instructions, available from www.schneider-electric.com, for installation instructions and specifications.
- See the PM8000 catalog pages, available from www.schneider-electric.com, or consult your local Schneider Electric representative for information about option modules available for your meter.

Option modules overview

Option modules are ordered separately from your meter, and can be connected to your meter without specialized equipment. Up to four option modules can be added to your meter.

Option modules are identified based on the physical order of the attached modules. The option module attached directly to the meter is module A, the module attached to module A is module B, and so on. The option module identifier is added to the ION module name and ION label to uniquely describe each possible combination of option modules.

A	Option module A
B	Option module B
C	Option module C
D	Option module D
E	Meter

For example, a meter with two option modules, consisting of an analog option module directly attached to the meter (A) and a digital option module attached second (B), describes the Q2 analog output of module A as Port A Q2 and the S3 digital input of module B as Port B S3.

Option modules support

Maximum number of option modules

Depending on the type and quantity of option modules attached to your meter, you may need to reduce your meter's maximum operating temperature.

For a panel mount meter, one limitation on the number of modules that can be attached is the physical strength of the meter mounting hardware. If your meter is mounted in an area subject to vibration or other physical stresses, your meter's ability to physically support multiple option modules and maintain a seal against the mounting surface may be affected.

NOTICE

EQUIPMENT DAMAGE

Do not exceed the maximum number of option modules.

Failure to follow these instructions will result in equipment damage.

Related topics

- See “Specifications” on page 181 for more information about the maximum number and type of attached option modules.

I/O option modules

I/O option modules provide increased digital and analog input/output (I/O) capabilities for your meter.

⚠ WARNING

UNINTENDED OPERATION

Do not use the meter for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

These I/O modules can be used to monitor the status of breakers, control analog or digital transducers, or receive signals that can be interpreted to provide WAGES data for your energy system. For applications requiring high accuracy, such as energy pulsing to verify accuracy, the digital output on the meter base is recommended.

Your meter’s digital and analog outputs may change state during a firmware upgrade. Option modules are offline during an option module firmware upgrade; they will not communicate to the meter and the outputs may change state during the upgrade process.

Analog I/O option modules

Your meter’s analog I/O option modules can measure and output either low voltage or current using standard analog transducers such as 4 - 20 mA current transducers.

Analog option module data viewing

To view analog option module data on your meter’s display, go to **Inputs/Outputs** and select either **Analog Inputs** or **Analog Outputs**. If there are no I/O of the specified type, an informative message is displayed.

To view analog option module data on your meter’s webpages, connect to your meter’s webpages, go to **Monitoring > Inputs/Outputs** and select either **Analog Inputs** or **Analog Outputs**. If there are no I/O of the specified type, an informative message is displayed.

Related topics

- See “Analog inputs/outputs” on page 141 for information about analog I/O.

Digital I/O option modules

You can add digital I/O option modules to increase your meter’s capabilities.

Digital option module data viewing

To view digital option module data on your meter’s display, go to **Inputs/Outputs** and select either **Digital Inputs** or **Digital Outputs**. If there are no I/O of the specified type, an informative message is displayed.

To view digital option module data on your meter’s webpages, connect to your meter’s webpages, go to **Monitoring > Inputs/Outputs** and select either **Digital Inputs** or **Digital Outputs**. If there are no I/O of the specified type, an informative message is displayed.

Related topics

- See “Digital inputs/outputs” on page 145 for information about digital I/O.

Option module troubleshooting

Your meter’s option modules operate sequentially; if one module is non-functional all downstream modules may be affected. If your meter cannot communicate with an option module, by default it cycles power to that module and all downstream modules, making multiple attempts to communicate. After the maximum number of communication attempts has been exceeded the meter will remove power to that module and all downstream modules.

When troubleshooting option modules, attach each option module directly to the meter and verify its operation. If each option module operates when directly connected, use combinations of modules or known good modules to help identify the issue.

Events related to option module initialization and operation are stored in your meter’s onboard event log. Perform an option bus reset to restart the option bus and re-initialize the option modules attached to your meter.

Information about your option module’s type, serial number, firmware version and present status is available in the Factory and Diagnostics modules.

Related topics

- See the *ION Reference*, available from www.schneider-electric.com, for more information about the Factory and Diagnostics modules.

Option module reset

During an option module reset, your option module may not operate normally, and digital and analog outputs may change state.

⚠ WARNING

UNINTENDED OPERATION

Do not use this meter for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

You can reset your meter's option module bus through the display or using ION Setup. This power cycles all the modules attached to your meter. If you have queued firmware updates for your option modules on your meter's internal FTP site, the firmware updates are performed. Your option modules do not operate normally during an option module reset.

By default, your meter is configured so that your meter automatically performs an option bus reset when needed to help keep the option modules operating normally. Contact Technical Support for instructions on changing this default configuration.

Related topics

- See "Meter resets" on page 153 for more information about the resets you can perform on your meter.

Chapter 7 Security

Security overview

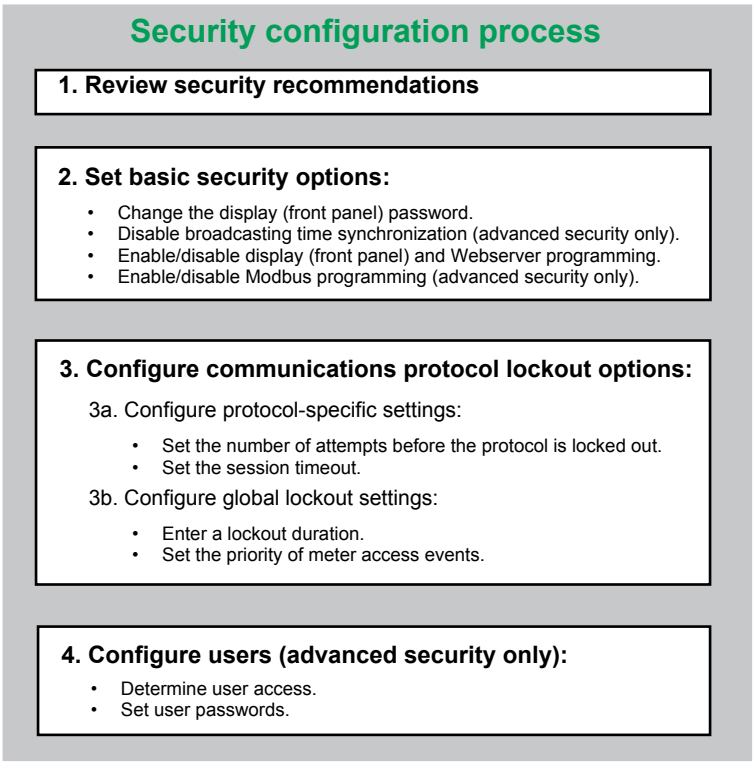
You can configure standard or advanced security on your meter, as well as optional revenue security.

Your meter comes with configurable security that you can set to either standard or advanced, which helps protect against unauthorized configuration of your meter and access to your meter's data through the meter's display or communications. Your meter has features that allow you to enable/disable Ethernet protocols and port numbers. Your meter also supports revenue locking, which incorporates revenue security on all revenue-related parameters and revenue sealing.

Your meter ships from the factory with standard security enabled.

Standard and advanced security features

Security allows you to configure the following security features to your meter:



Parameter	Standard/advanced	Details
Meter password	Standard/advanced	The meter's password is used to confirm user access when configuring the meter through the display or over communications. The default meter password is 0 (zero).
Active web server	Standard/advanced	This option allows you to enable or disable the ability to configure your device using webpages.
Allow Modbus programming	Advanced only	This option can only be enabled in advanced security and is disabled for standard security.
Allow front panel programming	Standard/advanced	This option allows you to enable or disable the ability to configure your device using the display.
Allow broadcasting time synchronization	Advanced only	This option can only be disabled in advanced security and is enabled for standard security.
Protocol lockout	Standard/advanced	This option allows you to configure the number of access attempts before lockout, lockout duration and meter access event priorities.

Advanced security user configuration

Advanced security allows you to configure users with specific access levels and passwords.

Security configuration process

The following is an overview of the process to configure security on your meter:

Communications protocol lockout overview

The communications protocol lockout security feature allows you to set the number of invalid login attempts that each user can make using a particular protocol and communications method before being locked out (a user is defined as a user login and password combination). For protocols that are not session-based (ION), you can configure how often the device registers invalid login attempts by configuring the session timeout. You can also configure the lockout duration for all configurable protocols.

NOTE: If protocol lockout is set to 0 (zero) there is no limit to the number of invalid login attempts and the protocol will never be locked out. However, the invalid login attempt events are recorded if the meter access events are configured to record invalid access attempts.

Session timeout specifies the active duration for a protocol; during this time, repeated invalid login attempts using the same USER/password combination are not registered (repeated invalid attempts with different combinations are still registered). Session timeout only applies to protocols which are not session-based and send credentials with each packet, and should be configured to help prevent accidental lockouts and filling the meter's event log with protocol access events.

Once a user is locked out, the device will not accept login attempts from that user on that protocol and communications method until the lockout duration has passed. Invalid login attempts accumulate until the user has completed a valid login or been locked out. For example, once USER01 has been locked out using ION over Ethernet, USER01 cannot access the device using ION over Ethernet until the lockout duration has

passed, even if USER01 enters the correct password. However, if the user enters the correct USER/password combination before being locked out, the invalid attempt counter is reset to zero. Even if the user is locked out using ION over Ethernet, that user can still access the device by entering the correct USER/password combination over a different protocol and communications method (for example, connecting to the device's RS-485 serial port using Modbus protocol).

Security recommendations and best practices

Recommended security configuration

The following meter configuration is recommended to help improve security on your meter.

- Ensure that your meter requires a password for configuration through the display or communications.
- Configure the protocol lockouts to help minimize access to your meter.
- Enable advanced security on your meter.
  - Configure users and passwords to help minimize access to your meter.
- Save a copy of your meter's ION Setup security configuration (*.scf) file in a secure location for future reference or troubleshooting. Your meter's security configuration file can be loaded onto other meters of the same type to configure their security settings.

Password best practices

- Change your meter's display (front panel) password from the default value of 0 (zero).
- Make your meter's display and user-specific passwords as complex as possible.
- Schedule regular changes to your meter's display and user passwords.
- Record your meter's display and user passwords in a secure location.

If your meter's user access information is lost, you must return the meter to the factory, where your meter is reset to its factory defaults and all logged data is lost.

NOTICE
DATA LOSS Record your device's user and password information in a secure location. **Failure to follow these instructions may result in data loss.**

Additional security recommendations

- Disable communications for all unused Ethernet network protocols.
- For the highest level of security, use a revenue-locked meter with advanced security enabled and configured for minimum access.
- Save a copy of your meter's security configuration (*.scf) file in a secure location for future reference or troubleshooting. Your meter's security configuration file can be loaded onto other meters of the same type to configure their security settings.
- Set your meter's time synchronization source to a secure communications port, and disable time synchronization on all other ports.

Related topics

- See "Protocols, ports and connections" on page 52 for more information about your meter's Ethernet network protocols.

Changing your meter's display password using the display

You can change your display password using your meter's display.

NOTE: The display password is also used as the webpage password if standard security is enabled.

1. Go to **Setup Menu > Password Setup**.
2. Configure your meter's display password.

Related links

- See "Setting up your meter using the display" on page 34 for instructions on how to configure your meter using the display.

Chapter 8 Communications

Your meter has one RS-485 connection and two Ethernet connections. The two Ethernet connections have the same IP address; you cannot connect your meter to two different Ethernet networks.

Ethernet communications

Connections

The meter supports a single IP address on both of its two physical Ethernet connections.

Related topics

- See your device's installation instructions, available from www.schneider-electric.com, for communication connection details.

Ethernet LEDs

Your meter has two LEDs that indicate the status of its Ethernet communications:

Link (data rate)	On: valid Ethernet connection • Yellow: data rate is 10 Mbps • Green: data rate is 100 Mbps
Act (activity)	Flashing green: data is being transferred

Related topics

- See your meter's installation sheet for Ethernet wiring information.
- See "Ethernet communications" on page 183 for your meter's Ethernet specifications.

Configuration

In order to use Ethernet communications, you must configure your device's IP address; you must also configure the subnet and gateway information if required by your network. You need to enter network information for any Ethernet servers used by the device (such as for SNTP time synchronization).

NOTE: Contact your network system administrator for your IP address and other Ethernet network configuration values.

Configure your device's Ethernet settings by using the display or directly connecting to your meter and using a web browser to access the device's webpages. Modify your meter's Ethernet settings to those provided by your network system administrator before connecting the device to your local area network (LAN).

After the meter's Ethernet port is configured and connected to the LAN, you can use ION Setup to configure other meter setup parameters

Related topics

- See “Setting up your meter using the display” on page 34 for instructions on how to configure Ethernet communications using your meter’s display.
- See “Self-discovery over Ethernet” on page 53 for instructions on how to connect to and identify your meter over a directly connected network.

- See the *ION Reference,* available from www.schneider-electric.com, for more information about the Communications module and its settings.

Protocols, ports and connections

The Ethernet protocols supported by your device allow simultaneous connections on the following IP service ports:

Protocol	Port (default)	Number of connections
ION	7700	8[1]
DNP	20000	
Modbus TCP	502	
Modbus RTU over Ethernet	7701	
Modbus TCP (dedicated)	502	32
EtherGate	7801	1
FTP	21 (20)	2
Webserver (HTTP)[2]	80	10
SNMP	161	N/A
SMTP server (email) outgoing only	25	1
NTP	123	1
IEC 61850	102	4

[1] These 8 simultaneous connections can be used by ION, Modbus TCP, Modbus RTU over Ethernet, or DNP. You can have a maximum of 3 DNP connections.

[2] This is used for the meter’s webpages.

By enabling or disabling TCP/IP protocols, you can control whether or not your meter accepts new socket connection requests from the TCP/IP protocols supported by the meter. Changing settings does not impact existing connections. Depending on the protocol, you can also change the port number.

If you configure communications so that you cannot communicate to and configure your meter, you must return the meter to the factory, where your meter is reset to its factory defaults and all logged data is lost.

NOTICE

DATA LOSS

Ensure you maintain sufficient access to communicate to and configure your device.

Failure to follow these instructions may result in data loss.

Related topics

- See “Protocols” on page 57 for more information about the protocols supported by your meter.
- See “Network settings” on page 90 for instructions on how to enable/disable your meter’s TCP/IP protocols using ION Setup.

Ethernet topologies

Your device's Ethernet ports have the same IP address. The second Ethernet port acts as an Ethernet switch to help simplify network connections and reduce installation time and costs, by having shorter Ethernet cable runs between devices without needing additional Ethernet routers or repeaters. Your Ethernet connection source should be installed in a location that helps minimize the overall Ethernet cable routing length and complexity of your network.

Each of your device's Ethernet ports has full transmit/receive bandwidth: this means they do not split the signal, so connecting both of your device's Ethernet ports should not impact your communications speed.

When wiring your meter's Ethernet communications, it is recommended to only use straight-line topology. If local network loop or ring Ethernet topologies are required, you must enable RSTP (rapid spanning tree protocol) for your meter's Ethernet communications to function.

Internet protocol (IP) versions and supported features

Your meter supports both IPv4 and IPv6 (local addressing).

Your meter supports DPWS (devices profile for web services). This feature allows for self-discovery of the meter when directly connected on IPv6 local area networks.

Related topics

- See "Configuring network communications using ION Setup" on page 90 for instructions on how to enable and disable IPv6 on your meter.

Self-discovery over Ethernet

When you connect your meter directly to your computer, your meter automatically appears on the network. By default, the meter is named PM8000_<last six digits of MAC address>.

NOTE: You do not need to configure your meter's IP address for self-discovery over Ethernet; an IPv6 address is automatically generated from your meter's MAC address and self-discovery takes place over IPv6.

For example, a meter with a MAC address of 0060784173393 appears on the network as PM8000_713393.

Double-clicking the meter's network icon takes you to the meter's webpages, where you can view data and perform basic meter configuration.

NOTE: For self-discovery, the meter must be connected directly to the computer using only a cable or switches, and not by a router.

Serial communications

The meter supports serial communications through the RS-485 port. Up to 32 devices can be connected on a single RS-485 bus.

In an RS-485 network, there is one master device, typically an Ethernet to RS-485 gateway. It provides the means for RS-485 communications with multiple slave devices (for example, meters). For applications that require only one dedicated computer to

communicate with the slave devices, an RS-232 to RS-485 converter can be used as the master device.

Serial protocols and ports

Your meter supports the following protocols on its RS-485 serial port:

Protocol
ION
Modbus RTU
Modbus Master
DNP 3.0
EtherGate
GPS: Truetime/Datum[1]
GPS: Arbiter[1]
GPS: Arbiter-Vorne[1]

[1] These protocol settings are for connecting to a GPS receiver communicating in serial ASCII format.

Related topics

- See "Protocols" on page 57 for more information about the protocols supported by your meter.

RS-485 connections

Your meter has one RS-485 connection.

Related topics

- See the "RS-485 communications" on page 183 for maximum devices and wire length.
- See your device's installation instructions, available from www.schneider-electric.com, for communication connection details.

RS-485 configuration

Before connecting your device to the RS-485 bus, use the meter's display, webpages or ION Setup to configure your meter's default RS-485 settings so that it has a unique unit identifier (address) and the following settings match the rest of the devices on the RS-485 bus:

- Protocol
- Baud rate
- Parity and stop bits

You can configure the following settings to help optimize communications performance:

- RTS delay
- RS-485 bias

You can use a communications converter (USB to RS-485 or RS-232 to RS-485) or an Ethernet gateway device to connect to your meter.

RS-485 bias

You can use the RS-485 bias setting to fine tune communications. Turn on the RS-485 bias when the meter is acting as a master over RS-485 communications and turn off the RS-485 bias when the meter is acting as a slave. You can configure RS-485 biasing through the meter's display or ION Setup.

RS-485 and gateway communications

Your meter can act as a gateway from the devices on the RS-485 bus to another communications port on the meter. For example, you can configure your meter as an Ethernet gateway, which lets you communicate through the meter's Ethernet port to the serial devices connected to the meter's RS-485 port using the ION protocol (EtherGate) or Modbus protocol (Modbus gateway).

Configuring communications using the display

You can configure your meter's basic communications settings using the display.

Before configuring Ethernet parameters, make sure you obtain your meter's IP address and other network information from your network administrator or IT department.

Before configuring serial parameters, make sure you have a unique unit ID for your meter and know the serial network settings (protocol, baud rate, parity and stop bits).

1. Go to **Setup Menu** > **Communications Setup** > **IP Address Setup**. Configure your meter's IP Address and other network information as required.

   NOTE: Your meter's default IP address is 169.254.0.10

2. Press the down button to access the next screen of meter communications settings and configure as required.

Chapter 9 Protocols

Protocols overview

Your meter supports several different protocols over its Ethernet and serial connections.

Your meter's default protocol implementation meets the needs of most systems with only basic configuration. You can customize these implementations to meet your specific needs; these are advanced procedures that require an understanding of ION architecture, the supported protocols, and the communications network and power system that your meter is connected to.

ION

ION is the native protocol and architecture of your meter. The basic building blocks of ION architecture are the ION modules, each of which is specialized to perform a specific task and contains data and instructions on how to manage that data. ION modules are combined (linked) together to create the meter's functions and features. ION modules that are linked together to perform a specialized task are called a framework, such as the Power Quality framework. These different functional frameworks are then grouped together to define the entire meter, and are collectively referred to as the device template.

Your meter ships with a default device template which provides extensive capabilities. You can also configure your meter's template to modify your meter's existing functions or to create new functions.

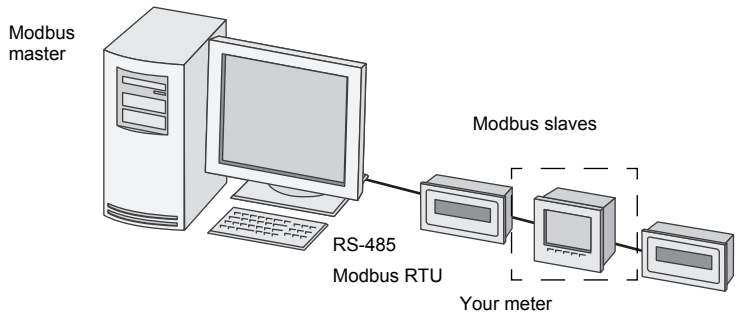
Modbus

Modbus is a master/slave communications protocol where the master initiates transactions and the slave(s) responds with the requested information or action. Your device can function as a Modbus slave or Modbus master, depending on how it is configured. Your device comes with Modbus slave functionality configured and ready to use. You can add custom Modbus information to the default Modbus slave data provided by your device.

Key terms

Term	Definition
Modbus gateway	A communications method that lets you communicate through an Ethernet gateway device to a Modbus serial network connected to that device.
Modbus master	A device that issues commands and receives responses from Modbus slave devices. Serial Modbus networks can only have one Modbus master per network.



Term	Definition
Modbus RTU	Serial Modbus protocol format; Modbus RTU transmits data using binary. Master and slave devices must use the same format.
Modbus register/address	Identifies the data to read/write. Modbus register maps are available for Modbus slave devices and detail the information available from the slave device. More than one register may be used to store a single value.
Modbus slave	A device that responds to Modbus commands and performs actions or provides information back to the Modbus master. Most Modbus networks contain multiple slave devices.
Modbus TCP	The Ethernet Modbus protocol format.
Modbus unit ID	The identifier for a slave Modbus device.

Your meter as a Modbus slave over Ethernet

Your meter as a Modbus master with serial Modbus slave devices

Your meter as a Modbus master with Ethernet Modbus slave devices

Supported features

Modbus data classes

Class	Description
Coils	Digital bits that can be read and written to
Input status	Digital bits that can be read
Input registers	16-bit integers that can be read
Holding registers	16-bit integers that can be read and written to

Modbus data formats

Format	Type	# of Modbus registers used
Unsigned 16-bit	Integer	1
Signed 16-bit	Integer	1
Unsigned 32-bit	Integer	2
Signed 32-bit	Integer	2
Unsigned 32-bit M10k	Integer	2
Signed 32-bit M10k	Integer	2
IEEE float[1]	Floating point	2
Packed Boolean for inputs	Integer	1
Packed Boolean for coils	Integer	1
Unsigned 16-bit read/write	Integer	1
Signed 64 bit	Integer	4

[1] Meters acting as Modbus masters support two versions of IEEE float with different word orders: high/low = Big Endian, low/high = Little Endian.

16-bit data (one word) is transmitted with most-significant byte first and least-significant byte second.

32-bit data (two words) is transmitted with the most-significant word first and the least-significant word second.

Modbus function codes

Function	Description	Master/slave
1	Read coil status	Master and slave
2	Read input status	Master and slave
3	Read holding registers	Master and slave
4	Read input registers	Master
5	Write to a coil	Master
6	Write to a holding register	Master and slave
15	Write to multiple coils	Master
16	Write to multiple holding registers	Master and slave
17	Report slave ID (serial only)	Master and slave
43 (subcode 14)	Read device identification	Master and slave
100	Read scattered holding registers	Master and slave

Modbus commands

A Modbus master command to unit ID 0 is broadcast (sent to) all Modbus slave devices. The only supported broadcast command is preset multiple registers.

For serial Modbus networks with only one slave device, the master can send commands using the single connection, one-to-one address of unit ID 248, regardless of the slave device's actual unit ID.

Modbus implementation

Modbus exception codes

Code	Name	Description
01	Illegal function	The requested command is invalid.
02	Illegal address	This code indicates one of the following: • The requested address is invalid for that function. • The requested address is not within the valid register range for this device. • The requested address is protected by device security.
03	Illegal value	This code indicates one of the following: • The requested value is not allowed for that register in the device. • The requested register is part of a multi-word value.

Modbus invalid read registers responses

Invalid type	Read response
Unmapped (unused)[1] register	0x8000
Reserved[1] register responses by type	
Signed integer 16-bit	0x8000
Unsigned integer 16-bit	0xFFFF
Signed integer 32-bits	0x80000000
Unsigned integer 32-bits	0xFFFFFFFF
Signed integer 64-bits	0x8000000000000000
Float32	0xFFC00000 (NaN = Not a number)

[1] Unmapped (unused) registers are registers that will never be used by the meter, and therefore have no defined format. Reserved registers have a defined format and are intended for use by the meter, its options or its variants.

Modbus invalid write registers response

If the meter receives a write command to a Modbus register address that does not have a register mapped, the meter does not respond. No data is written or stored, and the meter does not send back a rejection to the request.

If the meter receives a write command to a read-only Modbus register address, exception code 3 (illegal value) is returned.

Fixed and configurable Modbus map

Your device has a fixed (static) register map for meter data and a flexible, user-configured register map.

Modbus security

Your meter's onboard security options include Modbus-specific settings. These security settings may need to be configured in order to write Modbus data to the meter.

Modbus TCP ports

Port	Descriptions
502	Modbus TCP
7701	Modbus RTU over Ethernet

Modbus best practices

Serial

In order for your meter to operate as a serial Modbus device, you must complete the following prerequisites:

Prerequisite	Description
Wiring	The device's serial connection must be wired correctly. The Modbus slave devices must have communications wiring to the Modbus master.
Protocol	Slave: for your meter to be a serial Modbus slave, the meter's protocol must be set to Modbus RTU. Master and slave devices must use the same format. Master: for your meter to be a serial Modbus master, the meter's protocol must be set to Modbus Master.
Baud rate	The baud rate must be the same for all devices on the serial Modbus network.
Stop bits and parity	The communication stop bits and parity (for example, 8N1) must be the same for all devices on the serial Modbus network.
Unit ID	Each device on the serial Modbus network must have a unique unit ID (also called the device address).

Ethernet

In order for your meter to operate as an Ethernet Modbus device, you must complete the following prerequisites.

NOTE: You do not need to perform any Modbus-specific configuration for your meter to function as a Modbus slave device over Ethernet.

Prerequisite	Description
Ethernet	All devices must have a working Ethernet connection.
IP address	All devices must have a unique IP address.
Port	All devices must be communicating over Ethernet port 502 for Modbus TCP.

NOTE: Devices supporting multiple simultaneous Modbus TCP connections can have communications delays. Adjust your network timeout settings to accommodate this.

Modbus master

In order for your meter to operate as a Modbus master, you must complete the following prerequisites.

NOTE: These settings are required in addition to the serial or Ethernet Modbus prerequisites.

Prerequisite	Description
Modbus slave devices	All Modbus slave devices must be communicating and appropriately configured.
Protocol	• Modbus mastering serial devices: the master's serial port protocol must be set to Modbus master. • Modbus mastering Ethernet devices: the master must be communicating to the slave devices over Ethernet port 502.
Mastered devices	The Modbus master device must have the slave device information entered for mastering.

Modbus map

Your device's Modbus register information (map) is available for download from www.schneider-electric.com. The Modbus register information includes:

- registers and mapped values
- formats and scaling
- additional details where applicable

Configuring your meter for Modbus using the display

You can use the display to configure your meter as a Modbus slave or partially configure your meter for Modbus mastering.

NOTE: Before your begin, your meter's communications must be wired and configured.

Your meter does not require any Modbus-specific configuration to act as a Modbus slave device over Ethernet.

1. Navigate to **Setup Menu** > **Communications Setup** and select the serial communications setup screen.
2. Configure the serial port's Modbus parameters as required.

Parameter	Setting
Protocol	Modbus RTU or Modbus master
RS485 Bias	• Off if the meter is a Modbus slave • On if the meter is a Modbus master

3. Configure the meter's other serial port parameters as required.

   For Modbus master, you must add the Modbus slave devices using ION Setup.

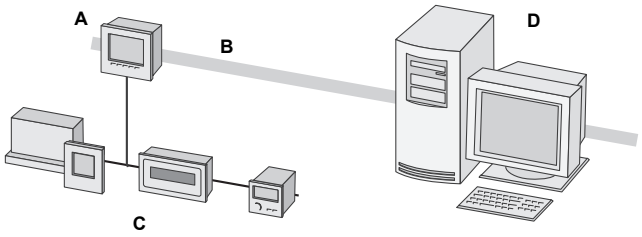
Ethernet gateway (EtherGate and Modbus gateway)

Ethernet gateway is a communications method that allows you to communicate through a gateway device to a serial network.

When a meter with gateway capabilities is installed on an Ethernet network, a master device (such as an energy management system) can communicate through the



gateway meter to a serial network of devices connected to the gateway meter's serial port(s). The maximum number of devices on the serial network is determined by the limitations of the gateway meter's serial port.

There are two types of Ethernet gateways that you can configure on your meter:

- EtherGate: a single TCP connection communicates through the gateway meter to a serial network of ION devices.
- Modbus gateway: up to a maximum of 32 Modbus master TCP connections communicate through the gateway meter to a serial network of Modbus devices.

EtherGate

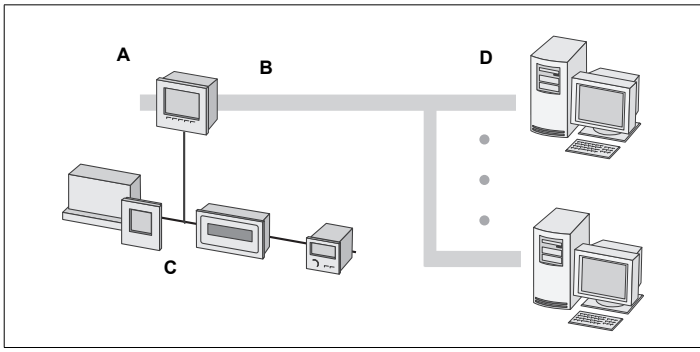
The meter can function as an Ethernet gateway (EtherGate). EtherGate is a protocol-agnostic communications method that lets you communicate through a gateway meter to a serial network of devices letting ION or other RTU over TCP data pass through the gateway meter to other networks, including third party systems. When a meter installed on the Ethernet network has EtherGate enabled, a master device (such as an energy management system) can communicate through the gateway meter to a serial network of devices wired to the gateway meter's COM port. You must create an additional communications connection to the gateway meter in order to read its information.

A	Gateway meter
B	Ethernet (single TCP connection)
C	Serial network of devices
D	Master device (one only)

For EtherGate, you must install the serial devices, configure them and connect them to your Ethernet-connected gateway meter. Ensure that each serial device is configured with the same protocol and baud rate and has a unique unit ID. Configure the gateway meter's serial port to use the EtherGate protocol, create the EtherGate site in ION Setup or an energy management system, and add the serial devices to the EtherGate site.

NOTE: EtherGate supports only one master device.

Related topics



- See "Configuring an EtherGate gateway using ION Setup" on page 93 for instructions on setting up an EtherGate gateway.
- See "Specifications" on page 181 for how many serial devices your meter can support.

Modbus gateway

In a Modbus gateway configuration, a Modbus master device can communicate using Ethernet through the gateway meter to downstream serial devices.

A Modbus request is sent through Ethernet using Modbus/TCP to the gateway meter. If this request is addressed with the slave ID of one of the downstream serial devices, the meter forwards the message to that device using Modbus RTU. When the downstream device responds, the gateway meter forwards the response back to the

Modbus master. In addition to Modbus slave addresses 0 - 247, the Modbus gateway supports slave address 255, which sends a Modbus request to the gateway meter only.

A	Gateway meter
B	Ethernet (multiple Modbus master TCP connections)
C	Downstream serial Modbus slave devices
D	Multiple Modbus master devices

The maximum number of Modbus gateway Ethernet connections available is equal to the number of Modbus TCP connections the gateway meter can handle.

For Modbus gateway, you must install the serial Modbus slave devices, configure them and connect them to your Ethernet-connected Modbus gateway meter. Ensure that each serial device is configured to communicate over Modbus with the same baud rate and has a unique unit ID. Configure the gateway meter's serial port to use the Modbus master protocol and enable the Modbus gateway feature, create a Modbus gateway site in ION Setup or an energy management system, and add the serial devices to the Modbus gateway site.

Related topics

- See "Configuring a Modbus gateway using ION Setup" on page 92 for instructions on setting up a Modbus gateway.
- See "Specifications" on page 181 for how many serial devices your meter can support.

Configuring EtherGate using the display

You can use the meter's display to configure a serial port to use the EtherGate protocol.

1. Navigate to **Setup Menu** > **Communications Setup** and go to the serial communications setup screen.
2. Set the serial port's protocol to EtherGate. Configure the other serial port parameters as required.

Related topics

- See "Setting up your meter using the display" on page 34 for instructions on how to navigate and use your meter's display.

FTP

Your meter has an internal FTP server where you can load custom webpages and other files onto your meter, and where the meter provides files created by meter features such as COMTRADE waveform records.

File transfer protocol (FTP) is a standard, client-server network protocol used to transfer files over TCP (Ethernet) networks.

NOTE: You can update the firmware on your meter's accessories using your meter's FTP site.

FTP memory allocation

Your meter's FTP memory usage changes when you copy a file to the meter's internal FTP site or modify a feature that uses the meter's FTP site.

If you attempt to load a file onto your meter's FTP site that is too large, your FTP program displays an error, and you must delete files from your meter's internal FTP site to free up memory before loading the file.

If you modify a meter feature which uses FTP memory, such as increasing the number of COMTRADE waveform records, the meter checks to confirm sufficient space is available on its internal FTP site before enabling the modified feature. If there is insufficient space, the feature is disabled, and you must delete files from your meter's FTP site to increase the available space before enabling the feature.

FTP file structure and permissions

Your meter's FTP folder structure is as follows:

- COMTRADE: you can read COMTRADE files from these folders, but you cannot delete or add files to these folders.
- IEC61850: you can add an IEC 61850 configuration (CID) file to this folder to activate the IEC 61850 protocol functions of your meter.
- optionModuleUpg and rmdUpg: you can load firmware update files for your meter's remote display or option modules into these folders.
- documents: this folder is intended for user storage. You can read, write and delete any type of files in this folder.
- web: this folder is where the meter's default webpages are stored and where you can add custom webpages to the meter by copying them into the appropriate sub-folders.

FTP filename requirements

FTP filenames are limited to standard ASCII characters, meaning that they cannot contain a blank space, quotation marks or \, /, *, ?, < or >, and are limited to 68 characters in length, including the file extension. The "/" character is only used as part of the FTP file directory information.

NOTE: FTP files from your meter can only be accessed and modified by Windows-based machines.

Supported FTP features

Ports

Port	Description
21	Command connection
20	Data connection (active and passive)

Your meter's command connection FTP port is configurable, and the data connection port is automatically assigned to the command connection port number minus 1.

FTP software

The recommended FTP software is Filezilla, WinSCP or Windows Explorer running on a Windows-based machine.

Related topics

- See “Specifications” on page 181 for the maximum number of FTP sessions and default timeout value.

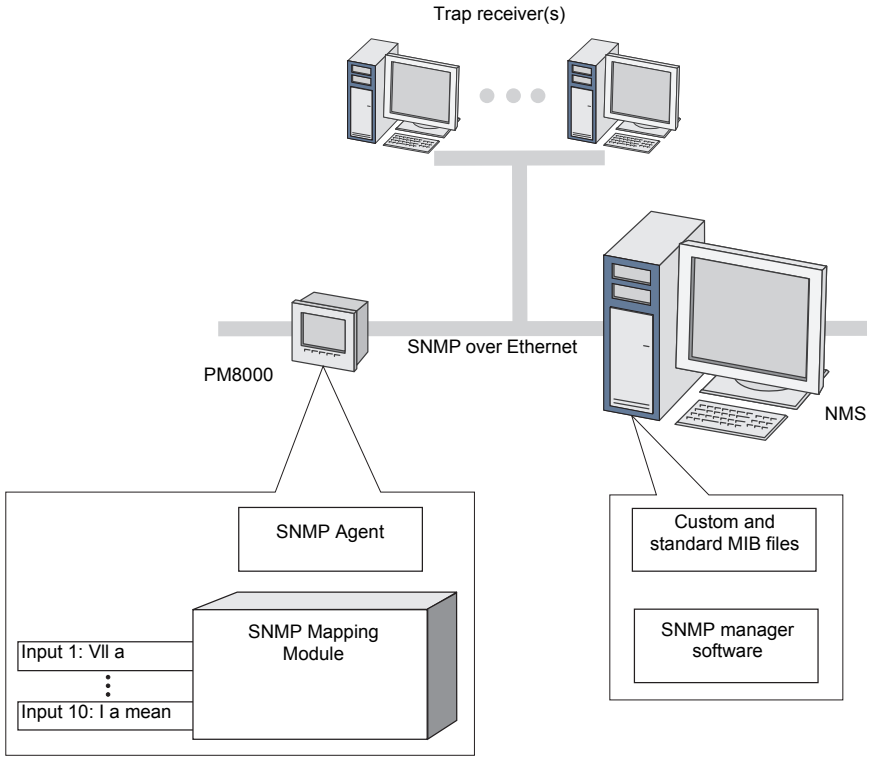
Accessing your meter’s FTP server

You must have FTP software such as Filezilla, WinSCP or Windows Explorer running on a Windows-based machine to transfer files to and from your meter’s internal FTP server.

1. Start your FTP software.
2. Connect to your meter via FTP by entering your meter’s IP address. Depending on your FTP software and meter security settings, you may be prompted for login credentials.

   NOTE: With standard meter security (no user configured), enter login credentials of 8000 and the meter password to connect to the meter. For advanced meter security, enter a valid user and password.
3. Navigate to the appropriate folder on your meter.
4. Close your FTP software to disconnect from the meter. The FTP connection automatically disconnects once the FTP timeout period has elapsed.

SNMP



Simple Network Management Protocol (SNMP) is part of the Transmission Control Protocol/Internet Protocol (TCP/IP) protocol suite. It is an application layer protocol that enables the exchange of network management information between devices, allowing you to manage network performance and to identify and solve problems on networks with devices of various types.

Your meter supports SNMP once you have enabled SNMP on your meter. You need to upload the your meter’s MIB file (available from www.schneider-electric.com) into the NMS managing your meter.

Key terms

Term	Definition
Agent	Software resident on the managed device which interfaces between the device and the NMS.
Managed device	Your meter in the SNMP network.
Community string	A text string that helps authenticate requests between the managed device and the NMS.
Managed object	Any parameter referenced in the MIB file, for example the parameters linked to the SNMP Mapping module on your meter.
MIB	A management information base which organizes the OIDs in a hierarchical tree.
NMS	A network management station, manager or client that executes applications to monitor and control devices. An NMS must have the standard and custom MIB files and SNMP manager software.
OID	An object identifier that uniquely identifies and labels a managed object in the MIB.
Trap receiver	An NMS that is configured to receive traps and whose IP address is an SNMP trap destination.

The meter in an SNMP system

SNMP implementation

MIB files

SNMP requires that you load your meter's ION MIB file (available for download from www.schneider-electric.com) into the NMS.

Your meter is compliant with MIB-II as defined by the standard MIB file RFC 1213. You must install RFC 1213, which is required to read basic network information for the meter (for example, TCP/IP traffic or number of packets received), if it is not included with your SNMP manager software.

Community strings

A community string is a text string which acts to help authenticate requests from the NMS to your meter. There are two community strings on your meter:

- Read Only Community: this community string is used by SNMP `get` (read-only) requests. The read only community string's initial factory-set value is **public**.
- Read Write Community: this community string is used by SNMP `set` (read/write) requests. The read write community string's initial factory-set value is **private**.

NOTE: You can also use the read write community string for SNMP `get` (read-only) requests.

If your meter receives an incorrect community string, it generates an AuthenticationFailure trap.

System strings

A system string is a text string which can be configured to provide information about your meter. There are three system strings on your meter:

- System contact: enter the name of the SNMP system administrator.
- System name: enter a descriptive name for your meter.
- System location: enter a description of your meter's location.

SNMP trapping

SNMP trapping allows your meter's agent to notify the NMS of events with an unsolicited SNMP message (a "trap" of the meter's alarm event). You can enter up to four IP addresses for SNMP trap notification for generic and enterprise-specific traps. For enterprise traps, you must also define the number of events or maximum time delay before SNMP traps are sent to the NMS.

SNMP trapping is only supported on SNMP v2.

Generic SNMP traps supported by your meter are:

- Coldstart: the meter (SNMP agent) is starting.
- Linkup: the SNMP agent is enabled.
- AuthenticationFailure: the meter (SNMP agent) has received an incorrect community value.

Enterprise-specific SNMP traps supported by your meter are:

- Low: trap of events with a low event priority.
- Medium: trap of events with a medium event priority.
- High: trap of events with a high event priority.

Trap	Event priority range
Low	64 - 127
Medium	128 - 191
High	192 - 255

NOTE: The number of events or maximum time delay settings only apply to enterprise SNMP traps.

SNMP Mapping module

The SNMP Mapping module is linked by default to the most commonly used meter values to make them available to SNMP. Modification of the SNMP Mapping module is an advanced procedure that should only be undertaken by those with an advanced understanding of SNMP, ION architecture and their meter's template.

Related topics

- See the *ION Reference,* available from www.schneider-electric.com, for detailed information on the SNMP Mapping, SNMP Options and Alarm Options modules.
- See "Configuring SNMP using your meter's webpages" on page 117 for instructions on how to configure your meter's SNMP functions using your meter's webpages.
- See "Configuring SNMP using ION Setup" on page 94 for instructions on how to configure your meter's SNMP functions using ION Setup.

Default SNMP mapping

Enabling SNMP provides SNMP access to the meter values linked to the SNMP Mapping module. You can configure the SNMP Mapping module to link to different meter values. By default, the following meter values are linked to the SNMP Mapping module:

I a	kVAR tot	Vll ca	Vln avg	Ib mean	kW sd mx del-rec
I b	kVA tot	Vll avg	Freq	Ic mx	kW sd del
I c	PF sign tot	Vln a	Ia mx	Ic mean	kW sd rec
I avg	Vll ab	Vln b	Ia mean	kW sd mx del	kW sd del-rec
kW tot	Vll bc	Vln c	Ib mx	kW sd mx rec	kVAR sd mx del
kVAR sd mx rec	kVAR sd mx del-rec	kVAR sd del	kVAR sd rec	kVAR sd del-rec	kVA sd mx del
kVA sd mx rec	kVA sd mx del-rec	kVA sd del	kVA sd rec	kVA sd del-rec	kWh del
kWh rec	kWh del-rec	kVARh del	kVARh rec	kVARh del-rec	kVAh del
kVAh rec	kVAh del-rec				

The following meter information is always provided by default and cannot be configured:

Voltsmode	Model number
Serial number	Device name
Firmware version	MIB version

If you change your meter's default values you must modify the custom MIB file to reflect the new values.

Changing your meter's default SNMP configuration assumes that you have an advanced understanding of ION architecture, SNMP, and the communications network and power system that your meter is connected to.

Related topics

- See the *ION Reference,* available from www.schneider-electric.com, for detailed information on the SNMP Mapping module.

Configuring your SNMP MIB file

You must configure your MIB file if you have modified the default SNMP information provided by the meter in order for the MIB file labels to reflect the modified values.

Download the ION MIB file from www.schneider-electric.com.

NOTE: You should only configure the variable name and description. Changing other fields in your MIB file may cause the client software to report problems or return errors when trying to retrieve or view parameters.

The variable name must conform to the following rules:

- The first character must be a letter.
- The first character must be lower case.
- The name must not contain any special characters such as *, ?, &.
- The name must not contain spaces.

1. Open your meter's MIB file in a text editing program (such as Notepad).
2. Update the variable name and description so they match the meter values connected to the SNMP Mapping module.

3. Save your meter's MIB file. Make sure you keep the original file extension of .MIB.

Example—This example shows an original and an updated OID entry in an MIB file, where the default meter value of voltage line-to-neutral phase A is modified in the meter's SNMP Mapping module and is now connected to voltage line-to-neutral phase C.

Original OID entry	
Vln_a	OBJECT-TYPE
SYNTAX	DisplayString (SIZE (0. . 255))
ACCESS	read-only
STATUS	mandatory
DESCRIPTION	"Host Meter Voltage Line A to Neutral Units = V (Volts)" ::= { schneiderElectric 34 }

You must update the variable name and description to match the meter values connected to the SNMP Mapping module:

Value	Original	Updated
Variable name	Vln_a	Vln_c
Description	"Host Meter Voltage Line A to Neutral Units = V (Volts)" ::= { schneiderElectric 34 }	Host Meter Voltage Line C to Neutral Units = V (Volts)" ::= { schneiderElectric 34 }

The SNMP client software reads the original and updated file as follows:

Original	Updated
variable name: Vln_a Description: "SNM1 Input 1 - Voltage (line-to-neutral) phase A"	variable name: Vln_c Description: "SNM1 Input 1 - Voltage (line-to-neutral) phase C"

IEC 61850

IEC 68150 is an Ethernet-based protocol designed for electrical substations. It is a standardized method of communications, developed to support integrated systems composed of multi-vendor, self-describing IEDs (intelligent electronic devices) that are networked together.

Your meter can be integrated into an IEC 61850 system as an IED (or server) supporting concurrent IEC 61850 client connections and an FTP connection (used for transferring data or configuration files).

- See the *ION Reference,* available from www.schneider-electric.com, for a description of the IEC 61850 ION modules.

Implementation

Your meter comes configured with a default set of meter data available to IEC 61850. This default set of meter data is used in the default data sets and reports in the ICD file(s) available for download from www.schneider-electric.com.

NOTE: Select the ICD file that matches your meter's option module configuration.

You must load a valid IEC 61850 configuration (CID) file into the meter's internal FTP site in order to activate the IEC 61850 features of your meter.

NOTE: Your meter can have only one IEC 61850 configuration (CID) file loaded onto its internal FTP storage. If additional CID files are loaded, IEC 61850 functions are deactivated until the additional files are removed.

Your meter has up to five dedicated IEC 61850 client connections.

You can load the IEC 61850 configuration file and configure the IEC 61850 custom modules using ION Setup.

COMTRADE

COMTRADE stands for COMmon format for TRAnsient Data Exchange defined by IEC 60255-24 edition 2001-05, and defines a common format for power quality event (disturbance) data in order to simplify retrieval, analysis and exchange of disturbance data between multiple sources and vendors.

The format of your meter's COMTRADE files is as defined by IEC 60255-24 edition 2001-05.

Your meter can automatically generate COMTRADE files and store them on the meter's internal FTP site. COMTRADE is configured as part of the default waveform recording but not enabled from the factory.

COMTRADE can be used in conjunction with IEC 61850.

NOTE: If you are generating COMTRADE waveform information, the associated waveform recorders cannot be modified unless COMTRADE is disabled. If the waveform recorders are not configured identically, COMTRADE waveform information will not be generated.

DNP

The Distributed Network Protocol Version 3.0 (DNP 3.0) is an open protocol used in the electric utility industry for communications and interoperability among substation

computers, Remote Terminal Units (RTUs), Intelligent Electronic Devices (IEDs, e.g. meters), and master stations.

Your meter can be integrated into a DNP network as a DNP slave.

Supported features

Your meter supports a maximum of three concurrent connections (sessions) using the DNP 3.0 protocol; one for each serial port, up to three using Ethernet, or a combination of both. Combinations available depend on the meter's communications options. A session consists of all incoming and outgoing DNP Master/Slave traffic on one of the meter's communications ports.

Default implementation

Your meter is pre-configured for basic DNP Slave functionality. For serial DNP communications, you must assign the DNP protocol to the appropriate serial communication port on your meter; you do not have to configure your meter’s Ethernet port(s).

You can modify your meter’s default DNP map using configuration software.

Importing data using DNP 3.0

Data can be imported into the meter from a DNP control relay or analog output device. This is an advanced feature intended for users with an in-depth understanding of the DNP 3.0 and ION protocols.

Chapter 10 Time and time synchronization

Your meter supports different time types and time synchronization methods to adjust its internal clock.

Time overview

Your meter's internal clock is used for keeping time, timestamping data and determining intervals for time-based measurements. The meter's clock does not affect externally logged data.

Your meter monitors the passage of time using the frequency of an internal oscillator or the frequency of the line power being measured. You can view your meter's time and date information using the display or through software. To improve your meter clock's accuracy, you can use an external time reference, such as a Global Positioning System (GPS) signal.

Your meter's battery maintains the internal clock when the meter is unpowered.

Your meter displays local time based on the meter's time sync source and settings for timezone and daylight savings time. You can configure your meter's date and time format.

Related topics

- See "Configuring time and time synchronization using ION Setup" on page 96 for instruction on configuring your meter's clock settings.
- See the *Time synchronization and timekeeping* technical note, available from www.schneider-electric.com, for more information about time formats and settings.
- See the *ION Reference,* available from www.schneider-electric.com, for a detailed description of the Clock module and its operation.

Time synchronization overview

The time synchronization source and the duration between time synchronization messages determines the accuracy of the meter's clock.

The clock is adjusted by synchronizing the meter's time with another time source. Time synchronization messages can be automatically generated and sent to your meter from your energy management system software or other time source such as an SNTP/NTP server or GPS receiver. You can also manually trigger a time synchronization message from your energy management system or configuration software.

NOTE: To help maintain data integrity, some energy management systems impose a blackout rule where time synchronization messages near energy interval boundaries are ignored.

Time synchronization sources

Use only one time synchronization source or method on each network to help prevent conflicting time synchronization information. For meters connected to energy management software, the same time synchronization method must be set for all meters connected to the system to help prevent timestamp inconsistencies.

NOTE: If you are configuring your meter clock remotely from another time zone, make sure you modify the meter's configuration to match local time.

For time synchronization sources with a resolution of one second or more, the meter time is only adjusted by a time synchronization message if the difference between the meter time and the message time is greater than one second.

Related topics

- See "Configuring time and time synchronization using ION Setup" on page 96 for instructions on configuring your meter's time synchronization settings.

Supported time synchronization sources

The following time synchronization sources are available to your meter:

- Meter configuration software (ION Setup): Configuration software can manually synchronize the time of your meter based on the clock of the computer running the configuration software. Configuration software synchronization is usually performed when the meter is initially commissioned.
- Energy management system: Energy management systems can synchronize the time of your meter to be consistent with other meters on the network.
- Simple Network Time Protocol (SNTP): SNTP can synchronize the time of your meter up to ± 1 second of other meters on an Ethernet network. For SNTP time synchronization, your meter must be connected to an Ethernet network that has an active SNTP server and be configured with the server's information.
- GPS receiver (IRIG-B): A GPS receiver using IRIG-B can synchronize the time of a meter up to ± 1 ms of Coordinated Universal Time (UTC). A dedicated serial network is required to implement a GPS scheme. For IRIG-B, one of your meter's digital inputs must be connected to the IRIG-B network, and the digital input must be configured for IRIG-B time synchronization in addition to configuring your meter's clock.

NOTE: Use the digital inputs located on the meter base for IRIG-B time synchronization and other high-accuracy applications.

- GPS over serial: A GPS receiver can synchronize the time of a meter up to ± 1 ms of Coordinated Universal Time (UTC). For GPS over serial, your meter's serial port must be connected to a GPS receiver, and the serial port communications must be configured with the correct protocol setting.
- Network Time Protocol (NTP): NTP can typically synchronize the time of a meter to ± 10 to 100 ms, depending on network configuration. To implement NTP time synchronization, your meter must be connected to an Ethernet network that has an active NTP server and be configured with the server's information.

Configuring time information using your meter's display

1. Go to **Setup Menu > Date/Time/Clock Setup > Date & Time Setup**.
2. Configure your time and date formats, time zone offset, and daylight savings time offset. Press the down button to access the Clock Setup screen.
3. Configure the clock and time synchronization source, and the time synchronization time format.

Chapter 11 Firmware and templates

You can load different firmware versions and templates onto your meter.

Firmware and template overview

Firmware is your meter's operating system that enables the functions of your meter. Your meter's template defines the meter's features such as its power measurement and analyzing functionality. Your meter ships from the factory with a default template, or you can customize your meter's template to create features specific to your meter's application. You can save your customized template and upload it to other meters of the same type.

You can view your meter's firmware version on your meter's display, webpages and through ION Setup.

You can upgrade your meter's firmware and template using ION Setup. Firmware updates and new factory templates are available for download from www.schneider-electric.com.

Your meter and accessories do not operate normally during firmware and template upgrades.Your meter's digital and analog outputs may change state during a firmware upgrade. Option modules are offline during an option module firmware upgrade; they will not communicate to the meter and the outputs may change state during the upgrade process.

⚠ WARNING

UNINTENDED OPERATION

Do not use this device for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Loading firmware or template onto your meter clears the meter's recorded data.

NOTICE

DATA LOSS

Ensure that all important data has been recorded before uploading firmware or a template to your device.

Failure to follow these instructions can result in data loss.

Typical workflows

To update your meter to the latest available firmware and factory template:

- Download the latest firmware and template for your meter.
- Load the firmware onto your meter; the firmware upgrade process includes upgrading the meter template.

To take an existing meter out of service and replace it with a new meter:

- Save the template from the existing meter.
- Load the existing meter's template onto the new meter; the new meter will now have the customized features from the existing meter.

To update your meter's firmware without updating your meter's template:

- Save your meter's template.
- Download the latest firmware.
- Load the firmware onto your meter. When prompted for a template file, select the template you saved from your meter.

To update the firmware on your meter's remote display:

- Download the display firmware.
- Load the firmware onto the meter's internal FTP site using either an FTP program or ION Setup. The results of the firmware update are stored in the meter's event log.

To update the firmware on your meter's option module(s):

- Download the option module firmware; make sure that the firmware matches the option module type.
- Load the firmware onto the meter's internal FTP site using either an FTP program or ION Setup.
- Power cycle or perform an option bus reset to start the option module firmware upgrade.

NOTE: If the meter is power cycled or an option module reset is performed while there are option module firmware upgrade files loaded on the meter's FTP site, the option module firmware is upgraded.

Related topics

- Visit the company website at www.schneider-electric.com and search for "PM8000" to see the available firmware and templates.
- See "Loading meter firmware using ION Setup" on page 84 for more information about loading meter firmware.
- See the online ION Setup help for instructions on how to load meter templates.

Firmware overview

Your meter has the latest firmware loaded onto it at the factory.

Firmware is your meter's operating system. When new firmware is available for your meter, you can upgrade to the latest version to get the added features and functionality. The firmware version loaded on your meter is shown on your meter's display. You can use ION Setup to upgrade the firmware on your meter.

You must load a meter template as part of the firmware upgrade process. You can save your meter's existing framework before performing a firmware upgrade and then reload it back onto the meter if you do not want to change your meter's template.

Your meter's remote display and option module use firmware information from the meter, but they may also need to have their internal firmware updated if internal components change. To load and update to your meter's remote display firmware, you need to copy the file to your meter's internal FTP server.

You can download firmware files from www.schneider-electric.com.

Related topics

- See the online ION Setup help, available from www.schneider-electric.com, for more information on downloading, saving and loading your meter's template.

Laptop computer upgrade considerations

Laptop computers generally have different default power properties than desktop computers. Incorrect power options can adversely affect device upgrading because the connection between the laptop and the device must be maintained in order for the upgrade to proceed. If the laptop's hard disk shuts down or the laptop enters system standby mode, this connection is broken and the upgrade procedure must be restarted.

If you are upgrading your meter's firmware using a laptop computer, follow these guidelines:

- Plug the laptop computer into a wall outlet. Do not run the laptop on its battery.
- Configure the laptop's hard disks so that they do not shut down after a certain period of time (for example, set to "never").
- Turn off the laptop's power suspension (for example, system stand-by) and hibernate options.
- Disable the laptop's option to power down when it is closed. This prevents a shut down if the laptop is accidentally closed.
- Disable the laptop's screen saver; screen savers can burden the CPU.

Firmware upgrade considerations

Ensure that the firmware version you are upgrading to is compatible with your meter, and that the version number is greater than your existing firmware (or else you will downgrade your meter).

Your meter's existing template may not work with different firmware versions if significant meter features have been added or modified.

Remote display (RMD) upgrade behavior

Your meter's remote display will upgrade as soon as the upgrade file is put in the remote display upgrade folder on your meter's internal FTP site. It is deleted as part of the upgrade process.

NOTE: If your meter's remote display loses power during firmware upload, the display will revert to its original firmware and you will have to reload the firmware file.

The results of your remote display firmware upgrade are stored in your meter's event log. Detailed information about your remote display, such as serial number and firmware version is provided in the Factory module.

Related topics

- See “Remote display troubleshooting icons” on page 41 for a description of the icons displayed by the remote display when a display firmware upgrade is required.
- See the *ION Reference,* available from www.schneider-electric.com, for more information about the Factory module.

Option module(s) upgrade behavior

To upgrade option modules, you must load the upgrade file into the appropriate folder on the meter’s internal FTP site. The upgrade is triggered by either a power cycle or option module reset. After the upgrade is performed, the upgrade file is deleted from the meter’s internal FTP site before the option module is reset to run the new firmware. The option module firmware will not upgrade if more than one upgrade file is in the folder. The upgrade file must be the correct file type and match the type of module being upgraded.

All option modules do not perform their regular functions during firmware upgrade. If more than one option module is being upgraded, the firmware on the option module closest to the meter is done first, then the next closest, proceeding to the furthest module from the meter base requiring upgrading. A single option module firmware upgrade should not take more than five minutes.

The option module upgrade results are stored in your meter’s event log. Detailed information about the option module, such as serial number and firmware version is provided in the Factory module. Information about the option module type and details of the option module’s state is provided in the Diagnostics module.

Related topics

- See the *ION Reference,* available from www.schneider-electric.com, for more information about the Factory and Diagnostic module.

Loading remote display firmware using FTP

You can upload firmware to your meter’s remote display by loading the firmware upgrade file onto your meter’s internal FTP site.

You must have:

- Your meter’s remote display firmware upgrade (.BIN) file. You can download upgrade files from www.schneider-electric.com.
- The remote display connected to your meter, and have access to your meter’s internal FTP site.

1. Connect to your meter’s internal FTP site. Open the remote display upgrade (rmdUpg) folder.
2. Drag the remote display firmware file into the remote display upgrade folder. The file is immediately transferred to the remote display, and is not stored on the meter.
3. Watch your meter’s display to confirm the firmware upgrade is taking place
4. Review the remote display firmware upgrade details stored in the meter’s event log to confirm that the upload was successful.

Related topics

- See “Accessing your meter’s FTP server” on page 66 for instructions on how to connect to your meter using FTP.

Loading option module firmware using FTP

You can upload firmware to your meter’s option modules by loading the firmware upgrade file onto your meter’s internal FTP site.

You must have:

- Your meter’s option module firmware upgrade (.SI9) file(s). You can download upgrade files from www.schneider-electric.com.
- The option module connected to your meter, and have access to your meter’s internal FTP site.

Your meter’s digital and analog outputs may change state during a firmware upgrade. Option modules are offline during an option module firmware upgrade; they will not communicate to the meter and the outputs may change state during the upgrade process.

⚠ WARNING

UNINTENDED OPERATION

Do not use this device for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

NOTE: If your meter’s option module loses power during firmware upload, the option module will revert to its original firmware and you will have to reload the firmware file.

1. Connect to your meter’s internal FTP site. Open the option module upgrade (optionModuleUpg) folder.
2. Drag the option module firmware file into the appropriate option module folder. Repeat for all modules that you want to load firmware onto.
3. Power cycle or perform an option module reset to upload the new firmware to the option module(s).
4. Review the option module firmware update details stored in the meter’s event log to confirm that the upgrade was successful.

Chapter 12 ION Setup

This section details the device configuration you can perform using ION Setup.

ION Setup overview

ION Setup is a free, downloadable device configuration tool. Devices can be configured over communications links whether they are locally or remotely located.

Devices such as your meter, based on ION architecture, have two different configuration methods using ION Setup.

- The standard method uses the setup assistant; a user-friendly tool that walks you through the process of setting up your meter. It is the recommended method for most users.
- The advanced method allows you to view and configure the ION modules directly. This is an advanced procedure that should only be done by those users who are expert in ION architecture and the systems in which the device is installed.

In addition to configuring your device, you can generate reports and view real-time and logged data using ION Setup.

Basic configuration can be done using your device's display or web pages, but many features are configured using ION Setup.

You can download ION Setup from www.schneider-electric.com. It is recommended that you always upgrade to the latest version of ION Setup to help properly configure features available on your device.

⚠ WARNING

UNINTENDED OPERATION

Do not use this device for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Refer to the online ION Setup help for precautions and detailed information.

⚠ WARNING

INACCURATE DATA RESULTS

Verify that associated devices and ION Setup are configured correctly.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Performing resets and configuring features such as data or waveform recorders will clear recorded data.

NOTICE
DATA LOSS Ensure that all important data has been recorded before configuring device. **Failure to follow these instructions can result in data loss.**

- See the online ION Setup help, available from www.schneider-electric.com, for instructions on how to use ION Setup and how to connect to your device using ION Setup

ION Setup device communication

Your device communicates to ION Setup using the ION protocol through its RS-485 serial communications port or over Ethernet.

If you are communicating over Ethernet, there are IP service ports set to the ION protocol, so you do not need to perform any additional device configuration to access your device using ION Setup. If you are communicating over RS-485, you will need to set the serial communications protocol to ION as well as configuring the rest of your serial communications settings.

Related topics

- See “Serial communications” on page 53 for instructions on how to configure your meter’s serial communication.

ION Setup device configuration

The best practice for configuring your device is to go through all the screens in the setup assistant and fill in the appropriate information for each feature as you go. The setup assistant has on-screen information and step-by-step wizards to help guide you through the process of configuring your device’s features.

This section contains additional information for ION Setup configuration tasks that are unique or have been modified for your device’s features and settings.

Template screen

Loading meter firmware using ION Setup

You can load firmware onto your meter using ION Setup.

You can download firmware for your meter from www.schneider-electric.com.

You must load a meter template as part of the firmware upgrade process. You can save your meter’s existing template by navigating to **Template > Save to PC** in the ION Setup Assistant and clicking **Save** to save your meter’s template as a .DCF file. You can also use a template that you have saved from another meter of the same type, or download a factory template from www.schneider-electric.com.

Ensure that you record your meter's user and password information in a secure location before upgrading the meter's firmware. If your meter's user and password information is lost, you must return the meter for factory reconfiguration, which resets your meter to its factory defaults and destroys all logged data.

Your meter's digital and analog outputs may change state during a firmware upgrade.

⚠ WARNING

UNINTENDED OPERATION

Do not use this device for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

1. Obtain the meter firmware (.UPG) and framework (.DCF) that you want to load onto your meter. Save the files where they can be accessed by the computer running ION Setup.
2. Start ION Setup.
3. Open the Setup Assistant for your meter.
4. Select the Template screen.
5. Click the Firmware Upgrade tab, then click **Upgrade**. Enter your meter's password (if prompted) and click **OK**.
6. Navigate to the meter firmware (.UPG) file and click **Open**. Enter your ION Setup password when prompted and click **OK**.
7. Navigate to the meter framework (.DCF) file and click **OK**. The Template Paste Options dialog box appears. Select the check boxes for the settings you want to retain (not overwrite) and click **OK**.

   A dialog box describes the template upload and firmware upgrade progress, verifies the firmware, and finishes with an overview stating whether the firmware and framework were successfully uploaded onto your meter.

Loading remote display firmware using ION Setup

This procedure is specific to the DIN meters with a remote display, and cannot be performed on meters with an integrated display.

You can load updates to your meter's remote display firmware using ION Setup over an Ethernet connection.

You must have:

- Your meter's remote display firmware update (.BIN) file. You can download update files from www.schneider-electric.com.
- The remote display connected to your meter.
- FTP access to your meter from the computer running ION Setup.

NOTE: If your meter's remote display loses power during firmware upload, the display will revert to its original firmware and you will have to reload the firmware file.

1. Obtain the remote display firmware (.BIN) that you want to load onto your display. Save the files where they can be accessed by the computer running ION Setup.
2. Start ION Setup.
3. Open the Setup Assistant for your meter.
4. Select the Template screen.
5. Click the Firmware Upgrade tab, then click **Upgrade**. Enter your meter's password (if prompted) and click **OK**.
6. Navigate to where you have stored the remote display firmware. Select the Remote Display firmware file (*.BIN) as the file type. Select the remote display firmware (.BIN) file and click **Open**. Enter your ION Setup password when prompted and click **OK**.

   A dialog box describes the firmware upgrade progress, verifies the firmware, and finishes with an overview stating whether the firmware was successfully uploaded

Loading option module firmware using ION Setup

You can upload firmware to your meter's option modules using ION Setup over an Ethernet connection.

You can only upload firmware to the same type of module; if you have different types of option modules connected to your meter, you must perform the upload process for each module type.

You must have:

- Your meter's option module firmware upgrade (.SI9) file. You can download upgrade files from www.schneider-electric.com.
- The option module connected to your meter, and have access to your meter's internal FTP site.
- FTP access to your meter from the computer running ION Setup.

All option modules do not perform their regular functions during firmware upgrade; they will not communicate to the meter and the outputs may change state during the upgrade process.

⚠ WARNING

UNINTENDED OPERATION

Do not use this device for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

1. Obtain the option module firmware (.SI9) files that you want to load onto your option module(s). Save the files where they can be accessed by the computer running ION Setup.
2. Start ION Setup.
3. Open the Setup Assistant for your meter.
4. Select the Template screen.

5. Click the Firmware Upgrade tab, then click **Upgrade**. Enter your meter's password (if prompted) and click **OK**.
6. Navigate to where you have stored the option module firmware. Select the Option Module firmware file (*.SI9) as the file type. Select the option module firmware (.SI9) file and click **Open**. Enter your ION Setup password when prompted and click **OK**.
7. A dialog box describes the firmware upgrade progress, verifies the firmware, and finishes with an overview stating whether the firmware was successfully uploaded

Basic setup screen

There are no additional tasks specific to your device for this screen.

Security

It is strongly recommended that you change your meter's display (front panel) password from the default value of 0 (zero).

If your meter's display (front panel) or user passwords are lost, or if you configure communications so that you cannot communicate to and configure your meter, you must return the meter to the factory, where your meter is reset to its factory defaults and all logged data is lost.

NOTICE

DATA LOSS

- Record your device's display and user password information in a secure location.
- Ensure you maintain sufficient access to communicate to and configure your device.

Failure to follow these instructions may result in data loss.

Configuring standard security using ION Setup

You can fully configure standard and advanced security on your meter using ION Setup.

In order to change security settings, you must be logged into ION Setup with an appropriate ION Setup user level. You must also have the appropriate meter-level security access to configure meter security.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Security**. Select Security Mode and click **Edit**. The open dialog box appears.
4. Select the appropriate security configuration file (*.scf) to configure your meter:
   - Standard: allows you to configure basic security and communications protocol lockout.
   - Advanced: includes the standard security features and adds user access/ password security settings.

5. The standard options or advanced options configuration screen appears. Configure the security parameters as required, some parameters can only be configured using advanced security:

Parameter	Standard/advanced	Details
Meter password	Standard/advanced	Default meter password is 0 (zero).
Active web server	Standard/advanced	This option allows you to enable or disable the ability to configure your device using webpages.
Allow Modbus programming	Advanced only	This option can only be enabled in advanced security and is disabled for standard security.
Allow front panel programming	Standard/advanced	This option allows you to enable or disable the ability to configure your device using the display.
Allow broadcasting time synchronization	Advanced only	This option can only be disabled in advanced security and is enabled for standard security.

   Click **Next** to configure protocol access information. The protocol lockout screen is displayed.

6. In the protocol lockout screen select the protocols that you want to be protected by the protocol lockout function. Select each protocol and click **Edit** to configure the protocol-specific parameters:

Parameter	Values	Description
Protocol lockout	0 - 255	The number of invalid login attempts before access is denied. If protocol lockout = 0, there is no limit to the number of invalid login attempts and the protocol will never be locked out.
Session timeout	1 - 43200 minutes (30 days)	The interval between access checks for non-session based protocols.

7. Enter the lockout duration (in minutes).
8. Click **Events** to configure user access event priorities. The Event Priorities screen appears.
9. Configure the user access event priorities.
10. If you have selected standard security, click **Finish**. You are prompted to save your security configuration to a file which can be loaded onto other meters.

    NOTE: If you chose to save your security file, enter a descriptive name and click **Save**. It is recommended that you do not overwrite the default security files.

    If you have selected advanced security, click **Next** to configure user access and passwords.

Configuring users and passwords using ION Setup (advanced security only)

In order to change security settings, you must be logged into ION Setup with an appropriate ION Setup user level. You must also have the appropriate meter-level security access to configure meter security.

You must have configured the standard security settings on your meter using ION Setup.

This task assumes that you are in the user configuration screen in the security wizard in ION Setup.

1. In the user/passwords screen, select (check) the user that you want to configure to view the user access options.
2. Select the appropriate values to configure the user's access:

Access	Description
Time sync	The user can set the meter's time and time synchronization parameters.
Read	The user can view all parameters except the security configuration.
Peak demand reset	The user can reset peak demand values.
Test mode	The user can put the meter into test mode (not applicable to the PM8000).
Full meter config	The user can configure all aspects of the meter except demand resets, test mode or security.
Security config	The user can configure security.

   Some access levels require that multiple access options be selected.
3. Select the user and click **Password**. The password entry screen appears.
4. Enter the desired password and click **OK**.
5. Continue configuring user access and passwords for each unique user of the meter.

   NOTE: Select **Show password when user selected** to display the password associated with that user. This feature is intended to help ensure that the correct password is entered for each user.
6. Click **Finish** to save your security configuration to the meter. You are prompted to save your security configuration to a file which can be loaded onto other meters.

   NOTE: If you chose to save your security file, enter a descriptive name and click **Save**. It is recommended that you do not overwrite the default security files.

Loading an existing security configuration file (.scf) using ION Setup

You can load an existing security configuration file (*.scf) onto your meter using ION Setup. The *.scf file can be a configuration for either standard or advanced security and must be from the same model of meter.

In order to change security settings, you must be logged into ION Setup with an appropriate ION Setup user level. You must also have the appropriate meter-level security access to configure meter security.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to Security. Select Security Mode and click **Send**. The Open dialog box appears.
4. Navigate to the location of the *.scf file you want to load onto your meter. Select the *.scf file and click **Open**. The *.scf file is loaded onto your meter.

Serial Settings

Configuring your meter as a Modbus slave using ION Setup

You can configure your meter as a Modbus slave using ION Setup.

Your meter's serial connection must be wired and configured correctly. The same mode of serial communication must be used for all devices on the network.

Your meter does not require any Modbus-specific configuration to act as a Modbus slave device over Ethernet.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Communications** > **Serial settings**. Select the tab for the serial port you want to configure.
4. Highlight the parameter and click **Edit** to configure the serial port's Modbus parameters as required.

Parameter	Setting
Protocol	Modbus RTU or Modbus master
RS485 bias	• Off if the meter is a Modbus slave • On if the meter is a Modbus master

5. Configure the meter's other serial port parameters as required.

Network settings

Configuring network communications using ION Setup

You can configure your device's Ethernet settings using ION Setup.

If you are connected to your device over Ethernet, changing Ethernet configuration parameters without another method of configuration enabled may cause loss of communications with your device and render it inoperable. In this case a factory reconfiguration of your device is required, which resets your device to its factory defaults and all logged data is lost.

NOTICE

DATA LOSS

Ensure you maintain sufficient access to communicate to and configure your device.

Failure to follow these instructions can result in data loss.

1. Start ION Setup.
2. Open the Setup Assistant for your device.
3. Select **Communications** > **Network Settings** and click the **TCP/IP** tab.
4. Select a setting and then click **Edit**. Configure the settings (for example, IP address, subnet or gateway) to match your communications system.

Parameter	Value	Description
Ethernet device name	configurable	This name is associated with your meter when using DPWS. By default, it is the meter type and the last 6 characters of its MAC address (example: PM8000_354386).
Enable IPv6	Yes/no	Specifies if IPv6 is enabled or disabled.
IP address	Contact your local network administrator for parameter values.	The Internet protocol address of your device.
SubnetMask		The Ethernet IP subnetwork address of your network.
Gateway		The Ethernet IP gateway address of your network.
Rx timeout	configurable	Specifies the number of seconds the meter waits for communication acknowledgments.
Modbus TCP Idle Timeout	configurable	Specify number of seconds the meter waits before disconnecting an idle Modbus TCP connection.
Modbus Gateway	Disabled/COM1	Specify the port on which Modbus Gateway sends/receives Modbus TCP requests. Note: For Modbus gateway to function properly, the serial port protocol must be set to Modbus Master.
MAC address	Read-only	The media access control (MAC) address is factory set and is for reference only.

5. Click the **Protocols** tab.
6. Select a protocol and then click **Edit**. Select whether the protocol connection requests are accepted by the meter, and configure the port number. Existing connections are not affected, but any new connections must comply with the meter's latest settings.

   NOTE: The protocol port number is not configurable on all protocols.

3rd party protocols

Configuring custom Modbus data using ION Setup

You can configure your meter's Modbus map using ION Setup.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Communications** > **3rd party protocols** and click on the **Modbus slave** tab.
4. Select the map name and click **Edit**. The Modbus map editor is displayed.
5. Select a parameter and click **Edit** to configure:
   - the data associated with that register value
   - the register value
   - the register's format and scaling
6. Click **Add** to add a new Modbus register, **Delete** to remove a Modbus register, **Set Name** to create a new name for your Modbus map, or **Save As** to save your Modbus map as a separate file.
7. Click **OK**. Your Modbus changes are implemented on your meter.

Configuring your meter as a Modbus master using ION Setup

You can configure your device to Modbus master slave devices over serial or Ethernet.

Make sure your master and slave devices have the prerequisite communications wiring and configuration before configuring your meter as a Modbus master.

NOTE: Devices supporting multiple simultaneous Modbus TCP connections can have communications delays. Adjust your network timeout settings to accommodate this.

The meter as a Modbus master over TCP/IP attempts to communicate with a slave device for up to 100 seconds (as per the RFC1122 standard) before moving on to the next slave device.

1. Start ION Setup
2. Open the Setup Assistant for your meter.
3. Navigate to **Communications** > **3rd Party Protocols** and click on the Modbus Master tab.
4. Click **Add** to add a Modbus slave device. The Modbus Device dialog appears.
5. Enter the Modbus slave information:
   - Enter the Modbus slave device's name and a label suffix (if applicable).
   - Select the device type of the slave device from **Device Type**.
   - Enter the unit ID of the Modbus slave device into **Slave ID**.
   - Select the serial or TCP connection from **Connected via**. This is the connection from the Modbus master to the slave device.
6. Click **Connections**. The Modbus Master Connections dialog appears.
7. Select the tab that corresponds to the connection you are configuring (for example, if you selected TCP Connection 1 from **Connected via**, select the TCP 1 tab) and configure it based on the connection type.

Connection type	Configuration
Serial connection	Select the serial communications port that is connected to the Modbus slave devices from the Assigned Port list.
TCP connection	Enter the IP address of the Modbus slave device, making sure that the IP port is set to 502.

   Click **OK** to return to the Modbus Device dialog.
8. Click **OK** to add the slave device. The device now appears on the list. Repeat these steps to add all of your Modbus slave devices.

Configuring a Modbus gateway using ION Setup

You can configure Modbus gateway on your meter using ION Setup.

Before you begin, make sure you have completed the following tasks:

- Confirm the serial network of devices are wired and configured to have the same baud rate, serial port settings (for example, 8N1), and protocol (Modbus).
- Confirm each serial device has a unique unit identifier.
- Confirm the serial network of devices are connected to the gateway meter's serial communication port.
- Confirm your gateway meter is communicating over Ethernet.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Communications** > **Serial settings** and select the tab for the communications port that the serial network is connected to.
4. Select **Protocol** and click **Edit**. The protocol selection screen appears.
5. Set the protocol to Modbus Master.
6. Navigate to **Communications** > **Network settings** and select the TCP/IP tab. Select **Modbus Gateway** and click **Edit**. The Modbus gateway selection screen is displayed.
7. Select the communications port that the serial network is connected to (and you just set to use the Modbus master protocol) and click **OK**. The Modbus gateway connection is created.
8. Create an Ethernet gateway site to access the serial network of devices through your gateway meter.

Configuring an EtherGate gateway using ION Setup

You can configure EtherGate on your meter using ION Setup.

Before you begin, make sure you have completed the following tasks:

- Confirm the serial network of devices are wired and configured to have the same baud rate, serial port settings (for example, 8N1), and protocol (ION).
- Confirm each serial device has a unique unit identifier.
- Confirm the serial network of devices are connected to the gateway meter's serial communication port.
- Confirm your gateway meter is communicating over Ethernet.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Communications** > **Serial settings** and select the tab for the communications port that the serial network is connected to.
4. Select **Protocol** and click **Edit**. The protocol selection screen appears.
5. Set the protocol to **EtherGate**.
6. Create an Ethernet gateway site to access the serial network of devices through your gateway meter.

Creating an Ethernet gateway site using ION Setup

You can create an EtherGate or Modbus gateway site in ION Setup to view serial devices connected to your meter when it is functioning as an Ethernet gateway.

You must have Ethernet gateway communications configured and your gateway and serial devices connected and communicating.

1. Start ION Setup.
2. Right-click on your workstation icon and select **Insert Item**. The New Network item dialog appears.
3. Select **Site** and click **OK**. The New Site dialog appears.
4. Select the **General** tab and configure the site.

Parameter	Values/Options	Description
Name	-	Ethernet gateway site name
Comm Link	Ethernet	Ethernet communications
Ethernet options	Gateway	Ethernet gateway communications
Gateway Info: IP Addr	-	IP address of the Ethernet gateway meter
Gateway Info: Port	7801, 502	• 7801 for EtherGate • 502 for Modbus gateway

5. Click **OK** to create the site.
6. Right-click on your newly created site and select **Insert Item**. The New Network Item dialog appears.
7. Make sure your newly created Ethernet gateway site is selected in **Attach to**. Select **Device** and click **OK**. The New Device dialog appears.
8. Enter the details of your serial device. Click **OK** to add the serial device to your Ethernet gateway site. Repeat for all the serial devices on the gateway meter.

NOTE: Use a separate standard Ethernet connection in ION Setup to connect to and read data from your Ethernet gateway meter.

Configuring SNMP using ION Setup

You can enable SNMP and configure SNMP trapping using ION Setup.

You must download the ION MIB file from www.schneider-electric.com.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Communications > Network Settings** and select the **SNMP** tab.
4. Configure your meter's SNMP parameters by selecting the parameter and clicking **Edit**. Click **OK** in the editing screen to set the parameter value.

Parameter	Description
Enable SNMP	Enables or disables SNMP on your meter.
Enable Traps	Enables or disables SNMP trapping on your meter.
Trap Rcvr Addr1 - Trap Rcvr Addr4	Enter up to four trap receiver IP addresses where trap messages will be sent.
Read only community	Enter the community string used for SNMP get (read-only) requests.
Read write community	Enter the community string used for SNMP set (read/write) requests. **NOTE:** You can use the read/write community string for SNMP get (read-only) requests.

Parameter	Description
System contact	Enter the name of your SNMP system administrator.
System name	Enter a descriptive name for your meter.
System location	Enter your meter's location.

5. Review the rest of the SNMP information and modify if necessary.

Loading an IEC 61850 configuration file using ION Setup

You can load an IEC 61850 configuration (CID) file using ION Setup over an Ethernet connection.

You must have:

- The IEC 68150 configuration file stored in a location accessible by ION Setup. The configuration file is created by customizing the IEC 61850 device (ICD) file, which can be downloaded from www.schneider-electric.com.
- FTP access to your meter from the computer running ION Setup.

NOTE: Your meter can have only one IEC 61850 configuration (CID) file loaded onto its internal FTP site. If additional CID files are loaded, IEC 61850 functions are deactivated until the additional files are removed.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Communications > 3rd Party Protocols** and select the **IEC 61850** tab.
4. Highlight a parameter and click **Upload**. Navigate to where you stored your meter's CID file, select the file, and click **Open**.

   Your meter reviews the CID file to determine if it is valid. This process may take several minutes.

   The CID status indicates whether the meter has received and validated an IEC 61850 CID file and is operating as an IEC 61850 server.

Configuring additional data for IEC 61850 using ION Setup

You can map additional data to IEC 61850 using ION Setup.

You must have a valid IEC 61850 configuration file loaded onto your meter for IEC 61850 functionality, but it is not necessary for configuring additional data.

NOTE: You can configure additional data at any time, whether or not IEC 61850 is operating on your meter.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.

3. Navigate to **Communications > 3rd Party Protocols** and select the **IEC 61850** tab.
4. Select the information type that corresponds to the type of meter information that you want to add to your IEC 61850 data. Select analog for numeric information and digital for boolean or binary information. Click **Edit**. The custom configuration screen is displayed.
5. Select the desired meter value from those available. If the value you want is not shown, select **Show all available registers**.
6. Select an IEC 61850 leaf to associate with the meter data, and click **>>** to map the value. Click **<<** to unmap values. Click **OK** to send and save your changes to the meter.

Clock

Configuring time and time synchronization using ION Setup

You can set the time and date and configure the time synchronization settings using ION Setup.

NOTE: The clock screen is where you set the start date for the time of use feature.

NOTE: You must manually adjust the date and time information if the device is installed in a different time zone location from the computer running ION Setup.

1. Start ION Setup.
2. Open the Setup Assistant for your device.
3. Navigate to **Clock** and select the **Timezone** tab.
4. Select any parameter and click **TimeSync** to synchronize your device’s date and time with the computer that is running ION Setup.

   Click the **DST Settings** tab to modify your meter’s daylight savings time start and end dates, if required.
5. Select the parameter that you want to configure and click **Edit**. Enter the password if prompted.

Parameter	Value	Definition
Timezone	—	Sets the timezone based on the timezones available from the computer’s operating system. **NOTE:** This is also where you can synchronize your meter’s DST settings with the computer’s.
Time sync type	Local time or UTC	Specifies the time format of the time sync message • UTC: Coordinated Universal time: for the purposes of meter configuration, it is equivalent to Greenwich Mean Time (GMT). • Local time: the local time, with DST and timezone information applied.
Time sync source	COM1, Ethernet, Ethernet - ION, Ethernet - DNP, IRIG-B	Sets which device port accepts time synchronization messages. Time synchronization messages on other ports are ignored

Parameter	Value	Definition
Clock Source	Internal, Line frequency, COMM	Sets the source for the clock: • Internal: the meter's internal clock. • Line frequency: the frequency of the measured power system as the clock source. • COMM: the meter's communication port (used by the GPS time sync source).
DST Offset	Numeric Bounded Format/Elapsed Interval Format	Specifies the amount of time the meter clock is moved forward when entering Daylight Savings. A value of zero disables this feature and clock does not adjust for DST.
Start of the Week	Monday - Sunday	Specifies the start day of the week used for Trending and Forecasting. **NOTE:** Changing the start day of the week clears all trending and forecasting data.

For SNTP/NTP time synchronization, you must set the **Time sync type** to **UTC** and the **Time sync source** to **Ethernet**.

For GPS/IRIG-B time synchronization, you must set the **Time sync source** to **IRIGB** and the **Clock Source** to **COMM**.

6. For SNTP/NTP time synchronization, you must also enter the following information under **Communications** > **Network Settings** > **NTP**:

Parameter	Value	Definition
Enable NTP Time Sync	NTP, SNTP, No	NTP: specifies NTP time synchronization. SNTP: specifies SNTP time synchronization. **NOTE:** SNTP is recommended for revenue-related applications. No: neither NTP nor SNTP time synchronization are used.
NTP Time Sync Interval	Numeric value or elapsed interval value	Specifies how often the meter synchronizes over SNTP. **NOTE:** This parameter is not used for NTP.
NTP Event Logging Threshold (NTP only)	1000 to 1000000	Specifies the minimum time difference (in milliseconds) for a time synchronization to be logged as an event. This parameter can be configured to help prevent the meter's event log from being flooded with time synchronization events.
NTP Server	Server IP address or domain name	Specifies the IP address (or fully qualified domain name if DNS is active) of the SNTP or NTP server.

7. For serial GPS time synchronization, you must also enter the following information under **Communications** > **Serial settings**:

Parameter	Definition
Protocol	Select the GPS setting that matches your GPS receiver.
Baud rate	The recommended baud rate for GPS time synchronization is 9600 bps.
Serial port	The recommended stop bits/parity for GPS time synchronization is 8N1.

Energy pulsing

NOTE: This screen is where you can configure the energy pulsing for accuracy verification testing.

Configuring energy pulsing using ION Setup

You can configure your meter's digital output and energy pulsing LED for energy pulsing.

Ensure that the digital output port or energy pulsing LED is available for energy pulsing and not associated with another function.

When configuring your meter, the configuration interface may show all of the possible ports, regardless of what is physically available on your meter.

NOTE: For applications where accuracy is important, use the digital output or energy pulsing LED located on the base of the meter.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Select **Energy pulsing**.
4. Select **LED** and configure the following basic parameters for your meter's energy pulsing LED.

Parameter	Description
Source	The energy source used for LED energy pulsing.
W Kt	The amount of source energy required to make the LED pulse.
W Pulse Width	The minimum time in seconds between LED pulse transitions. **NOTE:** There is a minimum 50% duty cycle on all pulses.
Wh pulse ovrld	Pulsing normally indicates that the energy pulsing LED should be operating normally. Pulsing suspended indicates that the energy pulsing LED is not able to pulse quickly enough. Modify the W Kt value to decrease the number of energy pulses.

NOTE: Only configure parameters other than those described if you have advanced knowledge of ION and the power system your meter is connected to.

5. Select an energy pulsing source tab (such as Wh Del) to configure energy pulsing using your meter's digital output..

Parameter	Description
Kt	The amount of energy source required to make one pulse. For example, in the Wh Del tab, the Kt value would be amount of real energy delivered (Wh Del) per pulse.
Pulse Width	The minimum time in seconds between pulse transitions. **NOTE:** There is a minimum 50% duty cycle on all pulses.
Port	Select an output port from the list. Only available output ports are shown.
(source) ovrld	Pulsing normally indicates that the output port should be operating normally. Pulsing suspended indicates that the output port is not able to pulse quickly enough. Modify the Kt value to decrease the number of energy pulses.

NOTE: Only configure parameters other than those described if you have advanced knowledge of ION and the power system your meter is connected to.

Energy applications

Configuring conditional energy using ION Setup

You can enable and configure conditional energy settings using ION Setup.

When configuring your meter, the configuration interface may show all of the possible ports, regardless of what is physically available on your meter.

One of your device's digital inputs must be connected and configured to define when conditional energy is accumulated.

1. Start ION Setup.

2. Open the Setup Assistant for your meter.
3. Navigate to **Energy Applications** > **Digital Input Based**. Review the digital inputs assigned to applications to help ensure there are no conflicting usages.
4. Select **Conditional Energy** and click **Edit**. The **Conditional Energy Setup** screen is displayed.
5. Select **Enabled** to enable the conditional energy feature.
6. Click **Select** to define the digital input. The input's state determines whether conditional energy is accumulated. When this digital input is on, conditional energy is accumulated.

   NOTE: It is recommended to set **Assigned Input** to No Connection to disable the conditional energy feature by removing any port associations.
7. Click **OK** to save your configuration.

Configuring standard input metering using ION Setup

You can configure input metering with standard units and rates using ION Setup.

When configuring your meter, the configuration interface may show all of the possible ports, regardless of what is physically available on your meter.

NOTE: Your device's digital input must be connected to the input metering pulse source. Review the digital inputs assigned to applications to help you understand your existing configuration.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Energy Applications** > **Digital Input Based**.
4. Select the input metering channel you want to configure and click **Edit**. The **Input Metering Channel Setup** screen is displayed.
5. Select **Enabled** to enable the input metering feature.
6. Click **Select** to define which digital input is the pulse source for the input metering channel.

   NOTE: It is recommended to set **Assigned Input** to No connection to disable the input metering channel by removing any port associations.
7. Configure the remaining parameters as required.

Parameter	Description
Pulse Weight	Enter the value per pulse.
Units	Select the measurement units associated with the pulse.
Demand Period	Enter the frequency in minutes that input metering data is calculated in your energy management system.
Rate	Select the rate associated with the defined Units.
Source ID	Enter a data identifier. This value is added to the input metering channel's data to uniquely identify the data within your energy management system.

8. Click **OK** to save your configuration.
9. Configure your meter to log the input metering data if required.

Related topics

- See the ION Setup online help, available from www.schneider-electric.com, for instructions on how to add input metering data to your meter's onboard data logs.

Configuring custom input metering using ION Setup

You can configure input metering with custom units and rates using ION Setup.

When configuring your meter, the configuration interface may show all of the possible ports, regardless of what is physically available on your meter.

NOTE: Your device's digital input must be connected to the input metering pulse source. Review the digital inputs assigned to applications to help you understand your existing configuration.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Energy Applications** > **Digital Input Based**.
4. Select the input metering channel you want to configure and click **Edit**. The **Input Metering Channel Setup** screen is displayed.
5. Select **Enabled** to enable the input metering feature.
6. Click **Select** to define which digital input is the pulse source for the input metering channel.

   NOTE: It is recommended to set **Assigned Input** to No connection to disable the input metering channel by removing any port associations.
7. Clear the **Standard quantity** checkbox.The screen changes to display custom input metering parameters.
8. Configure the remaining parameters as required.

Parameter	Description
Pulse Weight	Enter the value per pulse.
Units	Enter the measurement units associated with the pulse. **NOTE:** Include source identification information by entering "@" followed by the source identifier.
Demand Period	Enter the frequency in minutes that input metering data is calculated in your energy management system.
Rate	Enter the rate associated with the defined Units.
Scaling	Select the scaling value based on the relationship between Units and Rate.
Time Base	Select the value and units to match the Rate.

9. Click **OK** to save your configuration.
10. Configure your meter to log the input metering data if required.

Related topics

- See the ION Setup online help, available from www.schneider-electric.com, for instructions on how to add input metering data to your meter's onboard data logs.

Configuring incremental energy using ION Setup

You can configure incremental energy using ION Setup.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.

3. Navigate to **Energy Applications** > **Incremental Energy**.
4. Select **Status** and click **Edit**. The incremental energy configuration screen is displayed.

   NOTE: To display parameters for configuration, select **Enable**.
5. Select the parameter to configure and click **Edit**.

Parameter	Range	Description
Status	Enable/disable	Enables the incremental energy feature
Start time	12:00 am to 11:59 pm	The incremental energy first interval's start time. The start time must be prior to the end time for energy accumulation.
End time	12:01 am to 12:00 am	The end time for incremental energy. The end time must be after the start time and be less than or equal to 12 am (midnight)
Interval duration	Configurable	The increment period for the incremental energy duration.

Your changes are made to the meter.

NOTE: Configuring any parameter resets the incremental energy values recorded by your meter.

Onboard I/O

⚠ WARNING

UNINTENDED OPERATION

Do not use this meter for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Configuring onboard digital inputs using ION Setup

You can use ION Setup to configure your meter's digital inputs.

Digital inputs are available on your meter. You can add more digital inputs using optional I/O modules.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **I/O** > **Digital Inputs**. The tabs correspond to each digital input. Click on the tab for the digital input you want to edit.
4. Configure the digital input by selecting the parameter and clicking **Edit**.

Parameter	Value/Range	Description
Input Mode	Pulse, KYZ, A/C, IRIG-B[1]	Specifies how the meter processes the signal: • Pulse: the meter counts an entire pulse (from off-on to on-off) as one input. • KYZ: the meter counts a transition (from off-on or from on-off) as one input. • A/C: the meter detects analog signals where the ON condition is based on the presence of an AC signal. • IRIG-B[1]: the meter detects an IRIG-B time synchronization signal.
Polarity	Inverting/Non-Inverting	Specifies if the signal from the digital port is inverted or not inverted.
Debounce	0.000 - 1.000	Specifies how long (in seconds) the signal must remain in a state to be considered a valid state change.
Port	Defined by your meter's hardware	Your meter's physical digital input port.

[1] IRIG-B can only be connected to one of the digital inputs located on the meter base, not an option module. You must also configure your meter's clock to use IRIG-B time synchronization.

5. Once the parameter has been configured, click **OK** to save the setting to the meter.

Related topics

Configuring onboard digital outputs using ION setup

You can configure your meter's digital outputs using ION Setup.

One form A digital output is available on the base of the meter. You can add more digital outputs using optional I/O modules.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to either onboard or expansion I/O, Digital Outputs, and select a digital output tab.
4. Configure the digital output by selecting the parameter and clicking **Edit**.

Parameter	Value/Range	Description
Source	Digital/Boolean	Link this input to the value that drives the state of the digital output. If Source is not linked, the digital output state is driven by the Force ON, Force OFF values.
Force ON	Pulse	Link this input to a pulse that forces the digital output on for the PulseWidth duration, regardless of the Source input.
Force OFF[1]	Pulse	Link this input to a pulse that forces the digital output off.
Normal[1]	Pulse	Pulsing this input will switch the driver of the digital output from Force ON to Source.
Polarity	Inverting/non-inverting	Specifies if the signal to the digital port is inverted or not inverted.
PulseWidth	0 - 2,000,000	Specifies the duration of the pulse, in seconds. Setting this parameter to 0 sets the digital output continuously on.
Port	-	The physical digital output port connection. Only available ports are shown.

[1] These parameters are only valid when pulse width is set to 0.

The digital output is configured.

Expansion Modules

Option I/O modules

You can configure your meter's I/O option modules using ION Setup.

The I/O option module screen has tabs corresponding to the four possible option module, based on how the option modules are connected to the meter. Each has tab an area where the module's ports are listed for viewing and configuration. The module's type and status is displayed.

Status examples	Description
None	No option module detected
Normal	The option module is operating normally
Option module added	A new option module is detected
Option module removed	The option module has been removed
Invalid SI9	The option module's firmware is not supported
Invalid card	The option module type is not supported

In the option module tabs you can also reset your meter's option modules. This power cycles all the option modules. Option module functions are not available during a bus reset and option module digital and analog outputs will change state.

⚠ WARNING

UNINTENDED OPERATION

Do not use this meter for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Configuring I/O option module analog inputs using ION Setup

You can configure analog inputs using ION Setup.

Analog inputs are available on the optional I/O modules you can connect to the base of your meter.

Calculate your zero scale and full scale values based on the analog source and the input range of your meter.

Make sure that the analog input port that you want to use is properly configured and connected to a valid external analog signal source.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Expansion Module > Option I/O Modules**, and select the module tab that corresponds to the option module with the analog input you want to configure.
4. Select the analog input channel and click **Edit**. The setup screen for that analog input is displayed.
5. Configure the analog input by selecting the parameter and clicking **Edit**.

Parameter	Value/Range	Description
Zero scale	0 to $\pm10^9$	The minimum source value that matches the minimum analog input signal.
Full scale	0 to $\pm10^9$	The maximum source value that matches the maximum analog input signal.
Port	-	The physical analog input port connection.
Mode	Voltage, current	Determines whether the analog input is monitoring voltage or current.

The analog input is configured.

Configuring option module analog outputs using ION Setup

You can configure option module analog outputs using ION Setup.

Analog outputs are available on the optional I/O modules you can connect to the base of your meter.

Calculate your zero scale and full scale values based on the measured value and the analog output range of your meter.

Make sure that the analog output port that you want to use is properly connected to an analog receiver.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Expansion Module > Option I/O Modules**, and select the module tab that corresponds to the option module with the analog output you want to configure.
4. Select the analog output channel and click **Edit**. The setup screen for that analog output is displayed.
5. Configure the analog output by selecting the parameter and clicking **Edit**.

Parameter	Value/Range	Description
Zero scale	0 to $\pm 10^9$	The minimum source value that matches the minimum analog output signal.
Full scale	0 to $\pm 10^9$	The maximum source value that matches the maximum analog output signal.
Port	-	The physical analog output port connection.
Mode	Voltage, current	Determines whether the analog output is putting out voltage or current

The analog output is configured.

Configuring option module digital inputs using ION Setup

You can use ION Setup to configure your meter's digital inputs.

Digital inputs are available on your meter. You can add more digital inputs using optional I/O modules.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Expansion Module > Option I/O Modules**, and select the module tab that corresponds to the option module with the digital input you want to configure.
4. Select the digital input channel and click **Edit**. The setup screen for that digital input is displayed.
5. Configure the digital input by selecting the parameter and clicking **Edit**.

Parameter	Value/Range	Description
Input Mode	Pulse, KYZ, A/C, IRIG-B[1]	Specifies how the meter processes the signal: • Pulse: the meter counts an entire pulse (from off-on to on-off) as one input. • KYZ: the meter counts a transition (from off-on or from on-off) as one input. • A/C: the meter detects analog signals where the ON condition is based on the presence of an AC signal. • IRIG-B[1]: the meter detects an IRIG-B time synchronization signal.
Polarity	Inverting/Non-Inverting	Specifies if the signal from the digital port is inverted or not inverted.
Debounce	0.000 - 1.000	Specifies how long (in seconds) the signal must remain in a state to be considered a valid state change.
Port	Defined by your meter's hardware	Your meter's physical digital input port.

[1] IRIG-B can only be connected to one of the digital inputs located on the meter base, not an option module.

6. Once the parameter has been configured, click **OK** to save the setting to the meter.

Configuring option module digital outputs using ION setup

You can configure your meter's digital outputs using ION Setup.

One form A digital output is available on the base of the meter. You can add more digital outputs using optional I/O modules.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Expansion Module > Option I/O Modules**, and select the module tab that corresponds to the module with the digital output you want to configure.
4. Select the digital output channel and click **Edit**. The setup screen for that digital output is displayed.
5. Configure the digital output by selecting the parameter and clicking **Edit**.

Parameter	Value/Range	Description
Source	Digital/Boolean	Link this input to the value that drives the state of the digital output. If Source is not linked, the digital output state is driven by the Force ON, Force OFF values.
Force ON	Pulse	Link this input to a pulse that forces the digital output on for the PulseWidth duration, regardless of the Source input.
Force OFF[1]	Pulse	Link this input to a pulse that forces the digital output off.
Normal[1]	Pulse	Pulsing this input will switch the driver of the digital output from Force ON to Source.
Polarity	Inverting/non-inverting	Specifies if the signal to the digital port is inverted or not inverted.
PulseWidth	0 - 2,000,000	Specifies the duration of the pulse, in seconds. Setting this parameter to 0 sets the digital output continuously on.
Port	-	The physical digital output port connection. Only available ports are shown.

[1] These parameters are only valid when pulse width is set to 0.

The digital output is configured.

⚠ WARNING

UNINTENDED OPERATION

Do not use this meter for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Configuring setpoint/standard alarms using ION Setup

You can use ION Setup to configure the standard alarm settings.

1. Start ION Setup
2. Open the Setup Assistant for your meter.
3. Navigate to **Alarming** and click the **Standard** tab.
4. Select a setpoint and click **Edit**.
5. Enter unit password and click **OK,** if required. The **Setpoint Setup** screen is displayed.
6. Configure the setpoint values as required.

Parameter	Value/Range	Description
By Percentage	By Percentage/By Value	When available, specifies if the Pickup and Dropoff entries are by percentage or by value. If the option is not available, pickup and dropoff entries are by value.
Force Off	Checked/Unchecked	Forcing the alarm off disables all functions of the associated input. To stop an alarm from being displayed without affecting other meter features, set the alarm priority to Info only.
Label	String value	When available, lets you modify the default label so it more clearly identifies the alarm. Letters, numbers, underscores are permitted. Spaces are not permitted.
Pickup	Numeric value	Use this setting to provide a value for when the alarm turns on.
Pickup Delay	Numeric value	This specifies the number of seconds the digital input must be in the alarm pickup state before the alarm turns on.
Dropout	Numeric value	Use this setting to provide a value for when the alarm turns off.
Dropout Delay	Numeric value	This specifies the number of seconds the digital input must be below the alarm dropoff state before the alarm turns off.
Alarm Priority	None, Info only, Low, Medium or High	Specifies the priority level of the standard alarm. To disable the alarm, set priority to Info only.
Custom Priority	0-255	Select custom priority to view and configure the event priority of the event associated with the alarm. The event log cutoff value is displayed for reference; priorities above the cutoff are stored in the meter's event log.

7. Click **Save** to save the settings to your meter.

Configuring sag/swell alarms using ION Setup

You can use ION Setup to configure the sag/swell alarm settings.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Alarming** > **Sag/Swell**.
4. Select a parameter and click **Edit**.
5. Configure the parameters as required.

Parameter	Value/Range	Description
Nominal voltage	1 to 999,999	Specifies the nominal voltage value used for sag/swell detection.
Voltage Swell%	Percentage of nominal	Specifies the swell limit expressed as a percentage of the nominal voltage.
Voltage Sag%	Percentage of nominal	Specifies the sag limit expressed as a percentage of the nominal voltage.
Nominal Current	1 to 999,999	Specifies the nominal current value used for sag/swell detection.
I Sag Pickup	Numeric value	Specifies the percentage the current must deviate from the nominal current in order to be classified as a sag.
I Sag Dropout	Numeric value	Specifies the additional amount that the current must recover in order to signal the end of the sag.
I Swell Pickup	Numeric value	Specifies the percentage the current must deviate from the nominal current in order to be classified as a swell.
I Swell Dropout	Numeric value	Specifies the additional amount that the current must recover in order to signal the end of the swell.

Configuring digital input alarms using ION Setup

You can use ION Setup to configure the digital alarm settings.

When configuring your meter, the configuration interface may show all of the possible ports, regardless of what is physically available on your meter.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate **Alarming** > **Digital Input**.
4. Configure the digital input alarm settings by selecting an input and clicking **Edit**. Some settings are not configurable and are grayed out.

Parameter	Value/Range	Description
Input	Input On/Input Off	Specifies the input state/alarm behavior: • Input On: the alarm is on when the digital input is on. • Input Off: the alarm is on when the digital input is off.
Force Off	Checked/Unchecked	Forcing the alarm off disables all functions of the associated input To stop an alarm from being displayed without affecting digital input features, set the alarm priority to Info only.
Label	String value	When available, lets you modify the default label so it more clearly identifies the alarm. Letters, numbers, and underscores are permitted. Spaces are not permitted.
Alarm Priority	None, Info only, Low, Medium or High	Specifies the priority level of the digital input alarm. To disable the alarm, set priority to Info only.
Custom Priority	0-255	Select custom priority to view and configure the event priority of the event associated with the alarm. The event log cutoff value is displayed for reference; event priorities above the cutoff are stored in the meter’s event log.

5. Click **Save** to save the changes to the meter.

Implementing alarm setpoint learning using ION Setup

You can use ION Setup to implement setpoint learning, which analyzes your power system and recommends settings.

NOTE: Your meter’s power system must be stable in order to learn valid setpoint values.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Alarming > Standard**.

   NOTE: You can manually configure setpoint values by selecting the setpoint and clicking **Edit**.
4. Select a setpoint and click **Learn**. The **Global Setpoint Learning** screen is displayed.
5. Select the setpoint tabs to view existing configured or learned setpoint information.
6. Click **Setup**. The **Alarm Learning Setup** screen is displayed.
7. Configure the learning parameters for each setpoint and click **Save**:

Parameter	Value/Range	Description
Install mode	Automatic, Manual	• Automatic: the learned values are automatically applied if valid. • Manual: the learned values are stored for you to review and enter.
Duration	1-365	Days for maximum learning duration

8. Click **Start All** to begin setpoint learning for all setpoints.
   – When setpoint learning is in progress, an asterisk is displayed next to the setpoint.
   – Click **Abort** to stop learning for a specific setpoint. To stop all setpoint learning, repeat for each setpoint tab.
9. Apply the learned setpoint values:
   – Automatic: the setpoint values are automatically applied unless the learning process has issues or the learned values are invalid.
   – Manual: navigate to **Alarming** > **Setpoints** and click **Learn**. On each setpoint tab, click **Install** to apply the learned values to that setpoint.

NOTE: If you click **Install** while learning is in progress (in either manual or automatic installation mode), it stops the learning process and prompts you for confirmation that you want to stop learning and install the learned values. Once you confirm, the learned values are automatically installed or prepared for manual installation.

Implementing sag/swell limit learning using ION Setup

You can use ION Setup to implement voltage sag/swell learning, which analyzes your power system and recommends settings.

NOTE: Your meter's power system must be stable in order to learn valid sag/swell limits.

You must have configured your meter's nominal voltage in order to learn valid sag/swell limits.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Alarming** > **Sag/Swell**.
4. Select the **Voltage Swell %** or **Voltage Sag %** and click **Learn**. The **Global Setpoint Learning** screen is displayed.

   NOTE: You can manually configure the limit values by selecting the parameter and clicking **Edit**.
5. Click **Setup**. The **Alarm Learning Setup** screen is displayed. Configure the learning parameters:

Parameter	Value/Range	Description
Install mode	Automatic, Manual	• Automatic: the learned values are automatically applied. • Manual: the learned values are stored for you to review and enter.
Duration	1-365	Days for maximum learning duration

   Click **Start** to begin sag/swell learning. Click **Abort** to stop learning.
6. Apply the learned sag/swell limits:
   – Automatic: the limits are automatically applied unless there are issues with the learning process.
   – Manual: navigate to **Power quality** > **Sag/Swell**. Select the **Swell limit %** or **Sag limit %** and click **Learn**. Click **Install** to apply the learned limits.

NOTE: If you click **Install** while learning is in progress (in either manual or automatic installation mode), it stops the learning process and prompts you for confirmation that you want to stop learning and install the learned limits. Once you have confirmed, the learned limits are automatically installed or prepared for manual installation.

Configuring waveform recording using ION Setup

You can configure waveform recording using ION Setup.

For waveform recording to trigger automatically, you must enter your system's nominal (normal) voltage and current values, and then the amount of deviation from the nominal required to trigger waveform recording.

Changing your meter's waveform recording configuration clears your meter's existing waveform records.

NOTICE

DATA LOSS

Ensure that all important data has been recorded before configuring waveform recording.

Failure to follow these instructions can result in data loss.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Alarming** and click the **Sag/Swell** tab. Configure your meter's sag/swell detection parameters:

Parameter	Value/Range	Description
Nominal voltage	0 - 999,999	Specifies the nominal voltage value used for sag/swell detection.
Voltage Swell %	Percentage of nominal	Specifies how much a measured value must exceed the nominal in order to be considered a swell.
Voltage Sag %	Percentage of nominal	Specifies how much a measure value must fall below the nominal in order to be considered a sag.
Nominal current	0 - 999,999	Specifies the nominal current used by Swell and Sag limit % for a current sag or a current swell.
Current Sag Pickup	Numeric value	Specifies the percentage the current must deviate from the nominal current in order to be classified as a sag.
Current Sag Dropoff	Numeric value	Specifies the additional amount that the current must recover in order to signal the end of the sag.
Current Swell Pickup	Numeric value	Specifies the percentage the current must deviate from the nominal current in order to be classified as a swell.
Current Swell Dropout	Numeric value	Specifies the additional amount that the current must recover in order to signal the end of the event.

4. Navigate to **Power Quality** and click the **Sag/Swell** tab to configure your meter's waveform recording parameters.

Parameter	Description
Sag/Swell depth	Specifies the number of records the sag/swell data log can hold
Waveform depth	Specifies the maximum number of waveform records stored on the meter.
Waveform format	Specifies the number of samples per cycle and the number of cycles that are stored in a waveform record.
Post event cycles	Specifies the number of cycles recorded after the waveform is triggered. NOTE: The maximum number of post event cycles cannot exceed the number of cycles in the waveform record.
Hysteresis %	Specifies the difference in magnitude between the start and end thresholds for a power quality event.

NOTE: COMTRADE status must be set to **Disabled** before modifying the waveform format.

Configuring COMTRADE waveform recording using ION Setup

You can enable and configure COMTRADE waveform recording using ION Setup.

COMTRADE is configured as part of the default waveform recording but not enabled from the factory.

Your meter's COMTRADE files' format complies with the standard defined by IEC 60255-24 edition 2001-05.

1. Start ION Setup.

2. Open the Setup Assistant for your meter.
3. Navigate to **Power Quality > COMTRADE**.
4. Configure the COMTRADE parameters:

Parameter	Value	Description
Status	Enabled/Disabled	Enabled: COMTRADE files are generated. Disabled: COMTRADE files are not generated.
Depth	1 or more	The number of COMTRADE records stored on the meter. • By default the oldest COMTRADE record will be overwritten by the newest record. • A message is displayed if the Depth value exceeds the available memory. • A single COMTRADE record uses approximately 45 kB of meter memory.

COMTRADE records are stored as read-only files on your meter's internal FTP server, and are deleted when you perform a Master reset of the meter.

NOTE: To configure waveform recording, you must disable COMTRADE, configure waveform recording, and then enable COMTRADE. COMTRADE records are not generated if the waveform recorders have inconsistent settings.

Downloading COMTRADE files using ION Setup

You can download COMTRADE waveform records from the meter's internal FTP server to another network location using ION Setup.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Power Quality > COMTRADE**.
4. Select the status parameter and click **Save**. The **Upload COMTRADE files** screen is displayed.
5. Select the criteria for the COMTRADE files you want to load from your meter's internal FTP site to another network location. Click **OK**.

   NOTE: If no COMTRADE files are downloaded, the ION Setup status bar provides a descriptive message.

- See "COMTRADE" on page 71 for additional information about COMTRADE format waveform data.

Custom displays

Creating custom displays using ION Setup

You can use ION Setup to program new custom displays.

1. Start ION Setup.
2. Open the Setup Assistant for your meter.
3. Navigate to **Custom Displays**.
4. Select **Custom Displays** from the **Front Panel** tab and click **Edit**. ION Setup loads your meter's display information into the **Display Editor** screen.

5. Rename, delete, or change the order of custom displays through the **Display Editor** screen. Click **New** to add a new display. Click **Edit** to bring up the **Display setup** screen, where you can configure new or existing custom displays.
6. Configure your screen type:
   - **Screen Type**: Specify the number of parameters displayed on the screen.
   - **Screen Title**: Enter the title to be shown at the top of your custom display.
7. Click **Edit** to select the displayed parameters. The number of parameters displayed is determined in the Screen Type selection described above.
8. Select your digit display properties:
   - **Resolution**: Specifies the number of decimal places displayed.
   - **Last Digit:** Specifies whether the last number is rounded or truncated.
9. Click **Send** to save the changes in the meter.

Verification

Performing meter resets using ION Setup

You can perform meter resets on your meter using ION Setup.

Revenue-locked meters must be unlocked to perform resets that impact revenue data.

Meter resets clear the meter's onboard data logs and other related information.

NOTICE

DATA LOSS

Ensure all important data from the device has been retrieved before performing a reset.

Failure to follow these instructions can result in data loss.

1. Open the Setup Assistant for your meter.
2. Select the **Verification** screen.
3. Select **Normal Mode** and click **Display**.
4. Select the desired tab in the **Normal Mode** dialog box. Depending on the tab selected, different resets are available.

Tab	Reset available
Energy	Master Reset
Rolling Demand	Peak Reset Master Reset
Volts, Amps and Power	Master Reset
Conditional Energy	Cnd Reset Master Reset
Input Metering	IM(n) Reset **NOTE:** n is the input metering number, for example IM1. Peak Reset Master Reset

5. Click the appropriate button to perform the reset.

For some resets, the meter indicates that the reset is in progress. Do not configure or power down your meter until it indicates that the reset is complete or some parameters may not be completely reset.

Configuring digital outputs for IEC 61850 control using ION Setup

You can configure your digital outputs so that they can be used for non-critical control via IEC 61850.

Your meter has a comprehensive default implementation of IEC 61850 which meets the needs of most systems with only basic configuration. You can customize this implementation so that IEC 61850 can be used to control your meter’s digital outputs; this is an advanced procedure that requires in-depth knowledge of your meter, its underlying architecture, and the system in which it is installed.

⚠ WARNING

UNINTENDED OPERATION

Do not use this device for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

1. Start ION Setup
2. Connect to your meter in advanced mode.
3. Navigate to the GGIO Onboard folder and double-click on the module in the right-hand pane.
4. Select the Setup Registers tab.
5. Select the *SPCS Control Mode* register that corresponds to the digital output you want to control through IEC 61850 and click **Edit**. A dialog appears.
6. Select IEC 61850 CTLVAL from the dropdown list and click **OK**.
7. Select the Inputs tab.

8. Select the digital output *Status* register for the digital output that you want to control through IEC 61850. Click **Delete**.

   NOTE: This digital input register must be deleted in order to prevent a circular reference that will cause the affected modules to go offline.

9. Click **Send** to send your changes to the meter.
10. Select the Setup Registers tab and confirm that the Digital Output module's setup registers are appropriately configured.
11. Select the Inputs tab.
12. Select the *Source* register and click **Edit**.
13. Navigate to the IEC 61850 GGIO Onboard folder and select the *SPCS.stVal* output register that corresponds to the digital output.
14. Click **OK** and **Send** to save your changes to the meter.

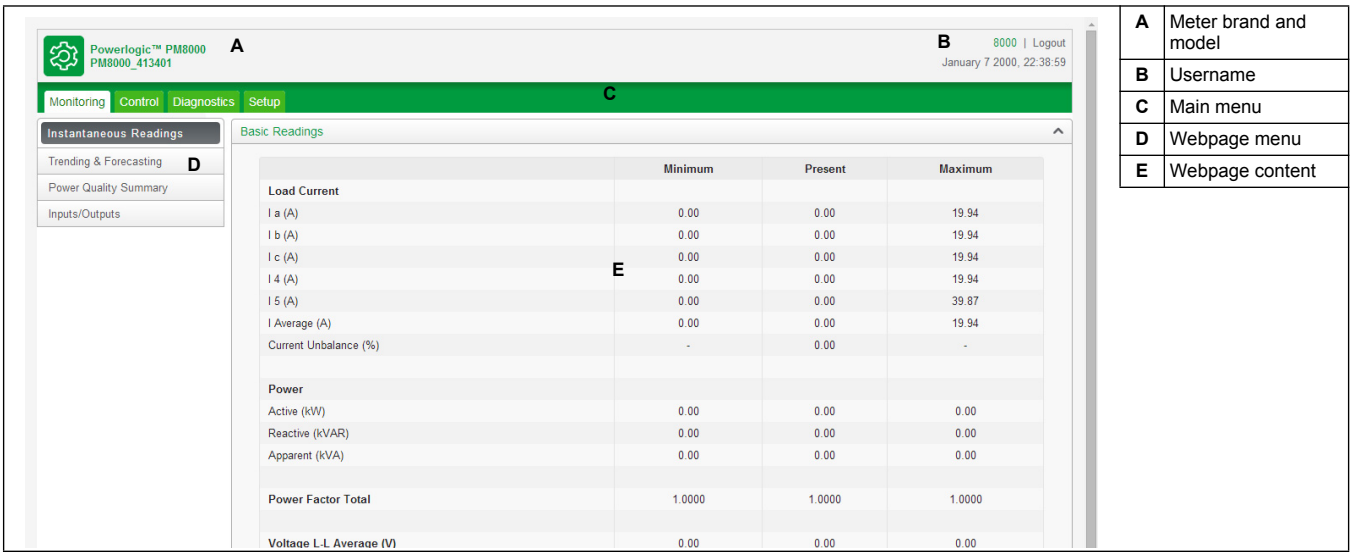
Chapter 13 Meter webpages

Overview

This section describes the meter's webpages. The meter's Ethernet connection allows you to access the meter so you can view data and perform trending and forecasting and some basic configuration using a web browser. You can also view standard filetypes through the meter's webpages and create custom webpages for your meter.

⚠ WARNING



INACCURATE DATA RESULTS

- Do not rely solely on data displayed on the display or in software to determine if this device is functioning correctly or complying with all applicable standards.
- Do not use data displayed on the display or in software as a substitute for proper workplace practices or equipment maintenance.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Webpage interface

Your meter comes with default webpages that contain the typical elements shown below.

A	Meter brand and model
B	Username
C	Main menu
D	Webpage menu
E	Webpage content

NOTE: This graphic is representative only, and your meter's webpages may appear differently than shown.

Default webpages

The following default webpages are available on your meter.

Main menu	Webpage menu	Webpage content
Monitoring	Instantaneous Readings	• Basic readings • Energy readings • Demand readings • Voltage readings • Power Quality
	Trending & Forecasting	Select the target and interval for trending and forecasting and view the results.
	Power Quality Summary	• Harmonics • ITI (CBEMA)-SEMI • NEMA Motor Derating Curve • EN50160
	Inputs/Outputs	• Digital inputs • Digital outputs • Analog inputs • Analog outputs
Control	Resets	Perform resets, and view when previous resets were performed.
Diagnostics	Statistics	• Communications • Ethernet • Serial port • Meter - Basic • Meter - Advanced
	Phasor diagram	View the phasor diagram and numeric values.
Setup	Ethernet	• Basic Settings • Advanced settings
	Serial Port	• Basic Settings • Advanced Settings
	SNMP Parameters	Configure your meter's SNMP parameters.
	NTP	Configure your meter's NTP parameters.
	SMTP	Configure your meter's SMTP parameters.
	Date & Time	Configure your meter's time and time synchronization.
	Preferences	Enter your meter's nameplate information.
	Metering	Configure the parameters that impact metered data.
Maintenance[1]	-	Custom. No default content.

[1] By default the Maintenance menu is empty, and the menu is not displayed until information is added to it.

Accessing the meter's webpages

You can access the meter's webpages through the meter's Ethernet connection using a web browser.

You must have cookies enabled in order to access your meter's webpages.

If you configure communications so that you cannot communicate to and configure your meter, you must return the meter to the factory, where your meter is reset to its factory defaults and all logged data is lost.

NOTICE

DATA LOSS

Ensure you maintain sufficient access to communicate to and configure your device.

Failure to follow these instructions may result in data loss.

1. Open a web browser and enter your meter's IP address in the address box. The webpage login prompt is displayed.

2. Enter a valid username and password, select your desired **Language** from the drop-down list, and click **Log In**. Your meter's webpages are displayed.

   NOTE: The username and password are defined by your meter's security configuration; if standard security is enabled, the password is the same as the display password with a default username of 8000. The default display password is 0 (zero). To help increase the security of your meter's configuration and data, configure your meter's username and passwords to be different from the default values.

   The meter's Monitoring webpage is displayed, showing real-time data.

3. Select the main menu tab that corresponds to the category of information you want to view, and select the webpage menu from the list on the left. The webpage content is displayed. Click the webpage content headings to expand and view the meter's data.

4. Select **Setup** to view and edit your meter's configuration.

Configuring SNMP using your meter's webpages

You can configure SNMP trapping using your meter's webpages.

You must download the ION MIB file from www.schneider-electric.com.

1. Connect to your meter's webpages.
2. Go to **Setup** > **SNMP Parameters**.
3. Configure your meter's SNMP parameters by selecting the parameter value.

Parameter	Range	Description
Enable SNMP	Yes/no	Enables or disables SNMP on your meter.
SNMP Port Number	161 (default)	Enter your meter's SNMP port number.
System contact	—	Enter the name of your SNMP system administrator.
System name	—	Enter a descriptive name for your meter.
System location	—	Enter your meter's location.
Read-only Community Name	—	Enter the community string used for SNMP get (read-only) requests.
Read-write Community Name	—	Enter the community string used for SNMP set (read/write) requests. NOTE: You can use the read/write community string for SNMP get (read-only) requests.
Enable SNMP Traps	Enable/disable	Enables or disables SNMP trapping on your meter.
Enable High Priority Alarms	Yes/no	Enables trapping of events that create high priority alarms.
Enable Med Priority Alarms	Yes/no	Enables trapping of events that create medium priority alarms.
Enable Low Priority Alarms	Yes/no	Enables trapping of events that create low priority alarms.
Report Buffer Size	1 - 30	Enter the maximum number of trap messages to be stored before the trap messages are sent. Traps are sent when the number of trap messages is equal to or greater than this value.
Report Hold Time	1 - 300 seconds	Enter the maximum duration for trap messages to be held. Trap messages are sent when the time after a trap event has occurred is equal to or greater than this value.
Trap Rcvr1 Addr - Trap Rcvr4 Addr	—	Enter up to four trap receiver IP addresses, where trap messages will be sent.

4. Click **Apply** to configure the meter's SNMP parameters.

Viewing files using your meter's webpages

You can load files of a variety of standard formats, such as *.pdf, *.jpg and *.png into the webpage folders on your meter's internal FTP site where they can be viewed using your meter's webpages. Videos in *.mp4 format can be played in most browsers. The filenames must be compatible with your meter's FTP filename requirements.

NOTE: Image files are shown at full-size (100%). Scale images to the desired size before loading them onto your meter's internal FTP site.

1. Access your meter's internal FTP site.
2. Open the web folder. Copy your file into the subfolder that corresponds to the webpage main menu tab you want to access your file from.
3. Connect to your meter's webpages. Select the main menu item that corresponds to the folder where you stored your file in step 2. Your file is listed in the webpage menu.
4. Select your file from the webpage menu to view.

Example

To view a schematic diagram (oneline.pdf) of your power system from the Monitoring menu of your meter's webpages:

1. Access your meter's internal FTP site.
2. Copy oneline.pdf into **web > monitoring**.
3. Access your meter's internal webpages and select the **Monitoring** menu. In the webpage menu click oneline.pdf to view your power system schematic.

Creating custom webpages for your meter

You can create custom webpages to view data or access configuration parameters from your meter.

Download the PM8000 Modbus registers map from www.schneider-electric.com.

1. Connect to your meter's internal FTP site.
2. Go to **web > examples**. Select samplereadings.html to create a data value webpage, or select sampleconfiguration.html to create a configuration parameters webpage.
3. Save a copy of the sample file. This filename is the webpage name.
4. Open your webpage in an HTML or webpage editor program.
5. Modify the webpage to reference the desired meter data or parameters from the Modbus registers map, and update the other fields where required. Save your custom webpage.

The meter will display translated content if it exists in the meter's memory. If translated content is not available, English is displayed.

6. Connect to your meter's internal FTP site.
   - If you have created a data viewing webpage, copy your custom webpage to **web** > **monitoring**.
   - If you have created a configuration webpage, copy your custom webpage to **web** > **setup**.
7. Login to your meter's webpages. Your custom webpage is available from the webpage menu under the monitoring (data viewing) or setup (configuration) tab.

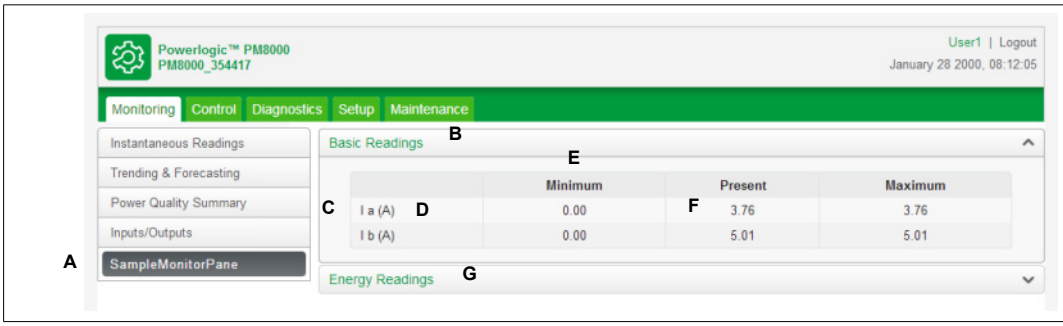
Sample data viewing webpage

You can create custom data viewing webpages using the sample webpage stored on your meter.

The sample webpages are stored in the documents folder on your meter's internal FTP site.

The PM8000 Modbus register map is available from www.schneider-electric.com.



If required, the PM8000 ION handles document is packaged with the meter firmware file which is available for download from www.schneider-electric.com.

The data viewing webpage must be stored on your meter's internal FTP site in the folder for Monitoring. The custom webpage is viewed by selecting the Monitoring main menu tab on your meter's webpage.

Configuring the HTML code other than where described is an advanced procedure and should only be performed by those with an advanced understanding of webpages and how your meter processes them.

Chapter 14 Trending and forecasting

Trending and forecasting overview

Trending and forecasting is a feature on your device that predicts the next set of measured or calculated data by plotting and analyzing trends in historical data.

Trending and forecasting data is a useful tool to help analyze changes in load and power quality and forecasting values such as demand. For your meter's trending and forecasting feature to work, you only need to give the meter time to accumulate data.

Related topics

- See the *ION Reference,* available from www.schneider-electric.com, for detailed information about the Trending and Forecasting module.

Trending and forecasting implementation

Data used for trending and forecasting is logged for the following intervals:

- Every hour for the last 24 hours
- Every day for the last month
- Every week for the last 8 weeks
- Every month for the last 12 months

The following parameters are configured for trending and forecasting by default:

kW sd del-rec (demand)	Freq (frequency)
Vll ab	I a mean
Vll bc	I b mean
Vll ca	I c mean
Vll avg	I avg mean

You can configure the start day of the week for trending and forecasting using ION Setup.

Related topics

- See "Accessing the meter's webpages" on page 116 for instructions on how to access your meter's webpages.
- See "Viewing trending and forecasting data on your meter's webpages" on page 127 for instructions on how to view trending and forecasting data.
- See "Configuring time and time synchronization using ION Setup" on page 96 for instructions on how to reset your meter's start day of the week.

Viewing trending and forecasting data on your meter's webpages

You can select data for forecasting and trending and view the resulting information using your meter's webpages.

For trending and forecasting to operate, your meter must have accumulated data for at least two of the specified intervals; for example, if you want to view a daily graph, your meter must have accumulated data for at least two previous days before the present day.

1. Log in to your meter's webpages.

2. Click **Monitoring** > **Trending & Forecasting**.
3. Select the **Target** and **Interval**. The graph for the selected data is displayed.

Chapter 15 Data, waveform and event logging

Overview

This section describes the meter's logging features. Your meter can support up to 50 logs (data recorders) which can each record up to 16 different parameters.

Your meter has a number of onboard default logs (also called data recorders) that are used to store data related to:

- Power quality and compliance
- Trending and forecasting
- Energy/revenue metering
- Meter events

Your meter also logs voltage and current waveform data when a sag or swell is detected. You must enter your power system's nominal values and configure your meter so that it can identify sags and swells. You can configure your meter's setpoint learning feature to learn your power system's normal operating values and use that information to help identify voltage sags and swells.

Logged data can be retrieved by energy management software.

Related topics

- See "Minimum configuration requirements for basic metering" on page 37 for information on entering your nominal values through the meter's display.

Default logging capacity

The following table summarizes the default logging depths and intervals for your meter's onboard data and waveform recorders:

Data recorder number	Log name	Depth	Interval
1	Revenue Log	3360 (35 days)	900 seconds (15 minutes)
9	Loss Log	3360 (35 days)	900 seconds (15 minutes)
2, 3, 4	Historic Logs	3360 (35 days)	900 seconds (15 minutes)
39	Daily Nominal Log	450	Triggered on demand
7, 8	Harmonics Logs	840 (35 days)	3600 seconds (1 hour)
N/A	Waveform recorders (6 total)	30	Triggered on demand
N/A	COMTRADE records	1	Triggered by waveform recording
10	Energy/Demand (EgyDmd Log)	3360 (35 days)	900 seconds (15 minutes)
5	Sag/Swell Log	100	Triggered on demand
N/A	Event Log	500	Triggered on demand
11, 12, 17, 19 - 26, 28, 29, 32, 35	EN50160 Logs	varies	EN50160 intervals
6, 16, 37, 38, 40	4-30 Logs	varies	IEC61000-4-30 intervals

Changing the log depths

Use ION Setup to change the number of records (depth) stored in the log. Changing how log records information (circular, or stop-when-full) is an advanced procedure to change the *RecordMode* setup register in the Data Recorder and Waveform Recorder modules.

Data logs and circular format waveform recorders have a minimum depth of 2 records.

Changing the log intervals

You can use ION Setup to change the logging intervals for the revenue and energy demand log.

Changing the interval for other data logs is an advanced procedure to modify the Periodic Timer module's *Period* setup register, which triggers the data log's recording.

Do not change the Periodic Timer module's *Sync Mode* setup register.

The default Periodic Timer modules that control the frequency of different data recording are as follows:

- Revenue Log Trg: controls the frequency of the logging of revenue values
- Loss Log Trg: controls the frequency of Loss Compensation Data logging
- EgyDmd Log Trg: controls the frequency of logging for the Energy and Demand Log (this log is used by ION Enterprise software to generate reports.
- Hist Log Trg: controls the frequency of Historic Data logging
- Harm Log Trg: controls the frequency of Harmonics logging

Programming your meter to write to any data recorder at continuous intervals shorter than 60 seconds (heavy logging configuration) can cause loss of data in the event of a power failure.

NOTICE

DATA LOSS

Use an uninterruptible power supply (UPS) if you program your meter for heavy logging.

Failure to follow these instructions can result in data loss.

Data log memory calculations

The amount of memory required to store data and event logs depends on the number of parameters being logged and the frequency with which these parameters are logged. The memory required is calculated as follows:

Memory consumption for each record (in Bytes) = [(number of parameters x 5) + 8]

For example, a data log recording three parameters consumes 23 Bytes of data. If the data is recorded every 15 minutes for 35 days, the data log requires approximately 80 kiloBytes of logging memory.

Waveform record memory calculations

The meter can simultaneously capture waveforms triggered by events on all channels to a maximum of 96 cycles for each waveform record. The memory required is calculated as follows:

Memory consumption for each waveform (in Bytes) = [2 x number of samples per cycle + 12] x [number of cycles in waveform x 2] + 32.

A single waveform record requires approximately 8 kB of memory.

Related topics

- See the ION Setup online help, available from www.schneider-electric.com, for more information about the logging memory allocations and other meter logging memory information displayed by the ION Setup Assistant.

Data logging overview

Your meter has data logging capabilities, including a special type of data log which is an event log, which logs prioritized events.

Data logs are recorded by your meter and stored in the meter's memory inside configurable data logs. Your meter's data logs are retained if the meter loses power.

Logged data can be used by energy management software. Logs can be configured to either overwrite the oldest data when full (circular), or to stop writing data to the log when the number of logged records reaches the maximum log depth (stop-when-full).

Your meter ships with a comprehensive data-logging configuration consisting of data logs set up to record values at specific intervals or on conditions. Your meter's default data logging configuration should be sufficient for most applications, but you can also reconfigure existing logs or create new logs for custom applications if needed.

Your meter can also be configured to email data log information.

Related topics

- See "Default logging capacity" on page 129 for details about your meter's default logging configuration.
- See the *Internal email client feature* technical note, available from www.schneider-electric.com, for instructions on how to configure your meter to email logged data.

Default data logging configuration

The default data logging configuration might be used by other components of your power monitoring system. Do not change the default configuration of any of the logs, unless you understand the impact of the change on these power monitoring system components and the data they use and on your meter's memory.

Revenue log

The Revenue Log is configured for use with UTS MV-90 billing software. The default values logged by the Revenue Log are as follows:

Parameter	Description
kWh del int	Interval kWh delivered
kWh rec int	Interval kWh received

Parameter	Description
kVARh del int	Interval kVARh delivered
kVARh rec int	Interval kVARh received

Historic data logs

Three historic data logs are used to record standard power system quantities, such as phase current, phase voltage and power factor. These logs are labeled Hist Mean Log, Hist High Log, and Hist Low Log. By default, they log the following values:

Hist Mean Log	
Vll ab mean	I avg mean
Vll bc mean	I 4 mean
Vll ca mean	kW tot mean
Vll avg mean	kVAR tot mean
V unbal mean	kVA tot mean
Ia mean	PF lag mean
Ib mean	PF lead mean
Ic mean	Freq mean

Hist High Log	
Vll ab high	I avg high
Vll bc high	I 4 high
Vll ca high	kW tot high
Vll avg high	kVAR tot high
V unbal high	kVA tot high
Ia high	PF lag high
Ib high	PF lead high
Ic high	Freq high

Hist Low Log	
Vll ab low	I avg low
Vll bc low	I 4 low
Vll ca low	kW tot low
Vll avg low	kVAR tot low
V unbal low	kVA tot low
Ia low	PF lag low
Ib low	PF lead low
Ic low	Freq low

Loss log

The Loss Log is configured to record loss values. By default, it logs the following values:

Parameter	Description
MU Ia^2h int	Phase A interval current squared hours
MU Ib^2h int	Phase B interval current squared hours
MU Ic^2h int	Phase C interval current squared hours
MU Vllab^2h int	Phase A interval voltage Line-to-Line squared hours
MU Vllbc^2h int	Phase B interval voltage Line-to-Line squared hours
MU Vllca^2h int	Phase C interval voltage Line-to-Line squared hours
MU Vln a^2h int	Phase A interval voltage Line-to-Neutral squared hours
MU Vln b^2h int	Phase B interval voltage Line-to-Neutral squared hours
MU Vln c^2h int	Phase C interval voltage Line-to-Neutral squared hours

Harmonics logs

Two harmonics logs record various harmonics data, including K-factor and Total Harmonic Distortion (THD). These recorders are labeled Harm Mean Log and Harm High Log. By default, they log the following values:

Harm Mean Log	
V1 THD mean	I1 K Fac mean
V2 THD mean	I2 K Fac mean
V3 THD mean	I3 K Fac mean
I1 THD mean	
I2 THD mean	
I3 THD mean	

Harm High Log	
V1 THD high	I1 K Fac high
V2 THD high	I2 K Fac high
V3 THD high	I3 K Fac high
I1 THD high	
I2 THD high	
I3 THD high	

Energy/Demand log

The Energy/Demand log records energy and demand data used by energy management software to generate reports. Changing the logged data can prevent the generation of reports that use this data.

Sag/swell log

The Sag/swell Log provides details of power quality events. By default, it logs the following values:

SS1 DistDur	SS1 DistV1Min	SS1 DistV1Max	SS1 DistV1Avg
SS1 DistV1Engy	SS1 DistV2Min	SS1 DistV2Max	SS1 DistV2Avg
SS1 DistV2Engy	SS1 DistV3Min	SS1 DistV3Max	SS1 DistV3Avg
SS1 DistV3Engy	SS1 DistNominal	SS1 Swell Lim	SS1 Sag Lim

EN50160 compliance logs

The EN50160 compliance logs are used to record EN50160 compliance parameters:

Data recorder	EN50160 component logged
EN50160 Frq/Mg	Power frequency and supply magnitude
EN50160 Hrm Vlt	Harmonics
EN50160 Intrp	Short/log interruptions
EN50160 Ovrvlt1	Temporary overvoltage
EN50160 Ovrvlt2	
EN50160 Prm-f/V	Parameter data (disabled by default)
EN50160 Prm-Vlr	
EN50160 Vunbal	Voltage unbalance

Data recorder	EN50160 component logged
EN50160 PrmHrm1	Parameter data (disabled by default)
EN50160 PrmHrm2	
EN50160 Vlt Dp1	Supply voltage dips
EN50160 Vlt Dp2	
EN50160 Vlt Dp3	
EN50160 Vlt Dp4	
EN50160 Vlt Dp5	

The meter logs EN50160 counter data for present and previous observation periods as well as EN51060 events.

4-30 compliance logs

Four 4-30 compliance logs are used to log parameters related to the International Electrotechnical Commission's IEC 61000-4-30 standards' power quality compliance and to create reports:

Data recorder	4-30 parameters logged
4-30 10m Log	• PqFlag • V1 • V2 • V3 • V1 THD (Total Harmonic Distortion) • V2 THD • V3 THD • NegSeqComp (Vneg/Vpos) • ZeroSeqComp (Vzero/Vpos) • Power Freq
4-30 10s Freq	• Power Frequency • PqFlag
4-30 2hr Log	• PqFlag • V1 • V2 • V3 • V1 THD (Total Harmonic Distortion) • V2 THD • V3 THD • NegSeqComp (Vneg/Vpos) • ZeroSeqComp (Vzero/Vpos) • Power Freq

Data recorder	4-30 parameters logged
4-30 3s Log	• PqFlag • V1 • V2 • V3 • V1 THD (Total Harmonic Distortion) • V2 THD • V3 THD • NegSeqComp (Vneg/Vpos) • ZeroSeqComp (Vzero/Vpos)
4-30 V Intrp DrtnAll	• Voltage interruption duration (all voltages)

Event log overview

Your meter records events produced by the meter's ION modules or external meter events.

Meter events, such as meter configuration or changes to I/O state, have priority values associated with them, so you can control what events are logged. Each event has a priority based on its type and severity, and for most events you can configure the priority. The event log records the date and time of the event, along with relevant details about the event.

Your meter's event log can be viewed through the meter's display and ION Setup.

Event log data example:

Date/Time	Cause	Value	Effect	Value

Default event log configuration

Your meter’s event log might be used by other components of your power monitoring system. Do not change the default event log configuration unless you understand the impact of the change on the power monitoring system components and the data they use and on your meter’s memory.

Changing the default event log configuration should only be undertaken by those with an advanced understanding of ION architecture and their meter’s template.

By default, your meter logs all configuration changes, meter access events, and power system events. You can configure certain features, such as the digital inputs, so an event is logged when the feature changes state (for example, the digital input changes from off to on).

The event log is controlled by the Event Log Controller module, which allows you to set a priority cutoff for event logging. Events with a priority number greater than the cutoff value are logged, and events with lower priorities are discarded. By default, this value is set so that all relevant events are recorded in the meter’s event log. Event priority values range from 0 to 255 with a typical cutoff value of 5.

NOTE: Alarms are generated by events from certain ION modules. The alarm level is determined by the priority of the associated event. To disable the alarm but still record the associated event, set the alarm priority to info only. To disable the alarm and the event, set the alarm priority to none.

Waveform recording overview

Your meter is able to record voltage and current waveform information.

Waveform information is used to help identify power system disturbances, which are an increasing concern for industrial plants, hospitals, data centers and other facilities where the equipment is sensitive to voltage or current sags, swells, and momentary interruptions. Waveform information is also used to help ensure compliance with power quality standards.

In addition to measuring and recording numerical values for voltage and current, your meter can also capture the sinusoidal waveform data. The current and voltage waveform data provides additional information for analysis of the system’s power quality or a power quality event.

You can manually trigger waveform recordings or configure them to trigger automatically when there is a power quality or power system event. For waveform recording to trigger automatically, you must enter your system's nominal (normal) voltage and current values, and then the amount of deviation from the nominal required to trigger waveform recording.

Your meter's waveform data storage format is defined by:

- Cycles: the number of cycles (based on your power system's frequency) included in the waveform (its duration).
- Samples: samples per cycle, which is the number of waveform data points collected in each cycle.

This gives you the option to record a lot of information for a very short duration or less information over a longer duration. You can also configure a delay in starting waveform recording which allows you to record pre- and post-event data.

You can use your meter to detect ITI (CBEMA) - type disturbances, and can determine information regarding the magnitude and duration of each disturbance. This information can be used by your energy management system to plot the disturbance on a CBEMA curve.

COMTRADE waveform data is available from your meter.

NOTE: If you are generating COMTRADE waveform information, the associated waveform recorders cannot be modified unless COMTRADE is disabled. If the waveform recorders are not configured identically, COMTRADE waveform information will not be generated.

Key terms

Term	Definition
COMTRADE	COMmon format for TRAnsient Data Exchange (COMTRADE) is a common format for waveform data.
ITI (CBEMA)	A curve that graphically describes an AC input voltage envelope which can be typically tolerated by information technology equipment. Meter waveform information is plotted on this curve to help evaluate power quality.
Nominal	The normal or usual parameter value. For example, the nominal voltage for many power systems is 120 V.
Sag	A power event where the voltage or current drops below the nominal value.
Swell	A power event where the voltage or current rises above the nominal value.

Default waveform recording configuration

Your meter's waveform recording operates once your nominal values are configured.

Your meter has the following default waveform recorders:

Waveform recorder	Description
Wfm Rc V1-Sg/Sw	V1 voltage waveforms recorded during a defined sag or swell event.
Wfm Rc V2-Sg/Sw	V2 voltage waveforms recorded during a defined sag or swell event.
Wfm Rc V3-Sg/Sw	V3 voltage waveforms recorded during a defined sag or swell event.
Wfm Rc I1-Sg/Sw	I1 current waveforms recorded during a defined sag or swell event.
Wfm Rc I2-Sg/Sw	I2 current waveforms recorded during a defined sag or swell event.
Wfm Rc I3-Sg/Sw	I3 current waveforms recorded during a defined sag or swell event.

Setpoint learning overview

Your meter can detect disturbances or values that are outside of a defined acceptable range. If you do not know what that acceptable range is or what threshold constitutes a voltage disturbance, your meter can learn these values by monitoring normal operating values to determine what constitutes a voltage sag or swell in order to help identify high and low setpoints.

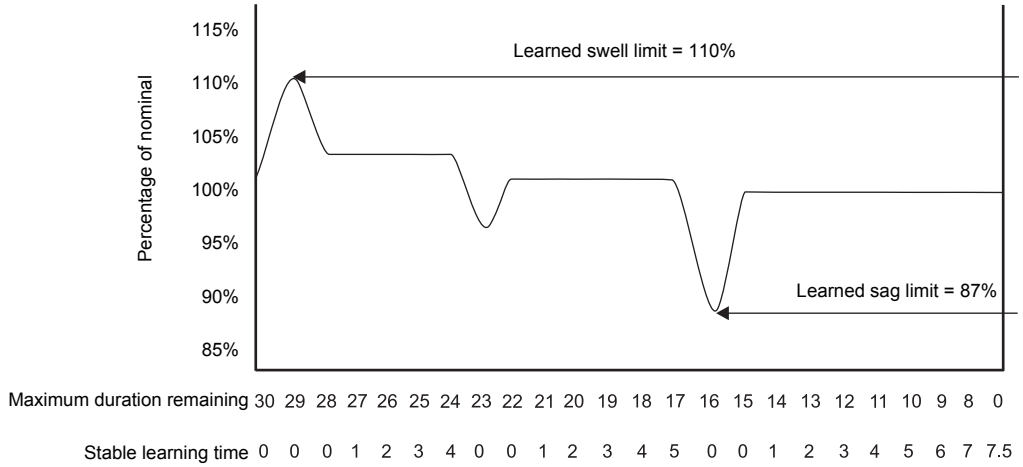
NOTE: To help your meter learn the most accurate values possible, it is important that learning occur during a period of normal operation. Do not schedule learning during a period of unusual operations in your system. Do not modify your meter's configuration during the learning period as it may stop the learning process.

You can configure the meter so that learned values are applied automatically once the learning period is complete or require that they are reviewed and manually applied. If a learned value is invalid, the learned values are not automatically applied, but logged for review.

Setpoint learning can be used to identify the following values:

Feature	Values
Setpoints (Alarms)	High limit Low limit Sustain until ON Sustain until OFF
Sag	Voltage sag limit
Swell	Voltage swell limit

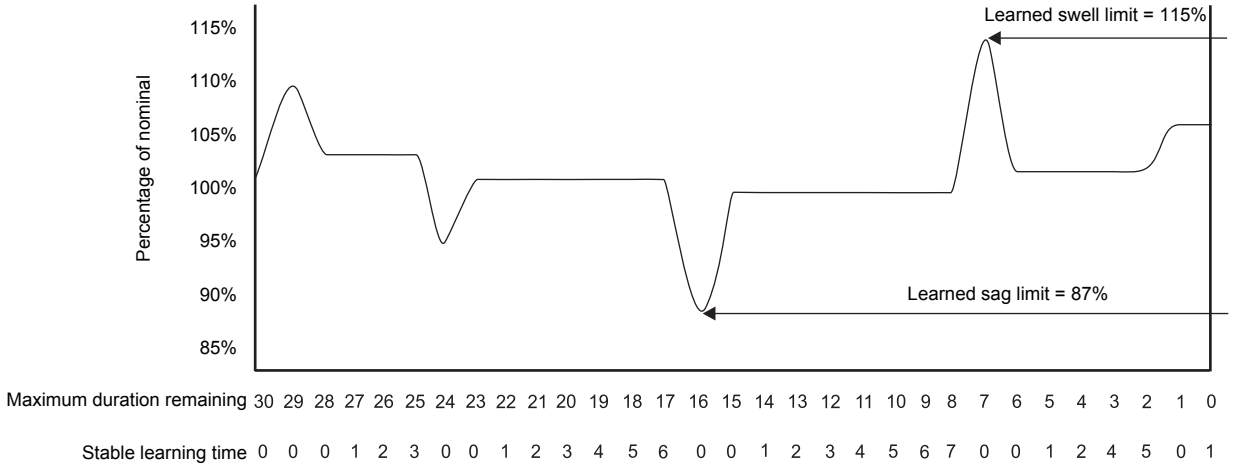
Learning installation mode and learning duration



There are two learning installation modes:

- Manual: the meter learns the applicable values but does not begin using the learned values. The learned values are recorded for review, and you can decide to use the learned values or adjust them as required before manually implementing the learned values.
- Automatic: the meter learns the applicable values and begins using those learned values automatically at the end of the learning period. If a learned value is invalid, the meter does not apply the value, but the value is recorded in the event log.

You can configure the maximum learning duration. The actual learning duration may vary, depending on the stability of the system. If the system is stable for a period equal to one quarter of the maximum learning duration, learning is complete; otherwise, the learning period will be the maximum learning duration.



Example: Setpoint learning duration in a stable system

In this example, the learning duration is 30 days. When the system is stable for 7.5 days (one quarter of 30 days) learning is complete.

Example: Setpoint learning duration in an unstable system

In this example, the learning duration is 30 days. Because the system is not stable for 7.5 days (one quarter of 30 days) learning is complete at the end of the maximum learning duration.

Chapter 16 Inputs/outputs

Inputs/outputs overview

Your meter has onboard digital I/O which can be increased by adding optional digital and analog I/O modules to expand your meter's I/O capabilities.

Your meter's digital and analog outputs may change state when being configured, during an option module reset or power cycle, or during firmware or framework upgrade.

⚠ WARNING

UNINTENDED OPERATION

Do not use the meter for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Your meter's inputs are used to monitor and receive signals from external sources, and its outputs are used to send signals to external sources.

Example:

- You can use a digital input to monitor a breaker to verify how many times the breaker trips. When the breaker reaches its limit for the number of trips, you can use the digital output to light an LED next to the breaker to help remind maintenance personnel know it is due to be replaced.
- You can use a digital output to pulse based on energy measurements.
- You can use an analog input to monitor an analog flowmeter to measure how much water flows through a pipe, and use the meter's analog output to send a signal to an analog-controlled valve to modify the valve position and change the flow rate.

Your PM8000 meter base has:

- 3 digital inputs
- 1 form A digital output
- 2 energy pulsing LEDs (one visible, one infrared)

You can view information about your meter's I/O through the display and webpages, and configure your meter's I/O using ION Setup.

NOTE: The digital outputs can handle voltages less than their specified maximum. For higher voltage applications, use an external relay in the switching circuit.

Related topics

- See your device's installation instructions, available from www.schneider-electric.com, for I/O wiring and installation instructions.

Input/output ION modules

You need to configure the following ION modules in order to use the meter's digital or analog I/O.

- Digital input: uses the Digital Input module, which tells the meter how to interpret incoming signals.
- Digital output: uses one of three ION modules depending on the application.
  - Digital Output module: monitors a change of state to control relay operation via a hardware output device.
  - Pulser module: transfers high-speed pulses to a hardware pulse counting device that is used to track energy usage.
  - Calibration Pulser module: integrates instantaneous power inputs, then outputs high-speed pulses to an LED that can be monitored for energy accuracy verification.

  NOTE: All of these modules can act as intermediaries between the physical hardware port and the other modules in the meter. They define the characteristics of the outgoing signals.
- Analog input: uses the Analog Input module, which tells the meter how to interpret an incoming analog voltage or current signal from transducers.
- Analog output: uses the Analog Output module to deliver a continuous direct voltage or current analog signal to transducers.

Input/output ION modules, ports and labels

You can configure the Digital Output, Digital Input, Analog Input, Analog Output, Pulser and Calibration Pulser ION modules to specify which port handles the outgoing or incoming signals. To assign a port to one of these modules, simply modify the *Port* setup register by picking a port from the enumerated list.

The following tables describe the ports that can be configured to handle outgoing or incoming signals:

ION module type	ION module name	Hardware port (device label)	Port name (ION label)	Description
Onboard digital output port				
Digital Output	Port D1	D1	Port D1	Form A output
Calibration Pulser	Wh Pulser -LED	N/A	kWh Pulse LED	Energy pulsing
Onboard digital input ports				
Digital Input	Port S1	S1	Port S1	Externally excited
	Port S2	S2	Port S2	Externally excited
	Port S3	S3	Port S3	Externally excited

ION module type	ION module name	Hardware port (device label)	Port name (ION label)	Description

- See “Option modules” on page 43 for a description of how the ports are named based on the option module location with respect to the meter base.

IRIG-B time synchronization

You can connect an IRIG-B time source to one of meter’s digital inputs for IRIG-B time synchronization; for improved accuracy use the digital inputs on the meter base. For IRIG-B time synchronization, you must configure both the meter’s digital input and the meter’s clock.

Related topics

- See “Configuring onboard digital inputs using ION Setup” on page 101 for instructions on how to set your meter’s digital inputs for IRIG-B time synchronization.
- See “Configuring time and time synchronization using ION Setup” on page 96 for instructions on how to configure your meter’s time synchronization settings for IRIG-B time synchronization.

Analog inputs/outputs

Your meter’s analog I/O option modules can measure and output either low voltage or current using standard analog transducers such as 4 - 20 mA current transducers.

For analog input operation, your meter takes an analog input signal and provides the resulting scaled value. For analog output operation, your meter takes an input value and scales it to the appropriate signal value to send out the physical analog output port.

You can view analog I/O values from your meter’s display or webpages.

Analog input voltage and current mode

In current mode, the analog inputs have a low input resistance while the meter is powered on, and a high input resistance when the meter is powered off. In voltage mode, the analog inputs have a high input resistance regardless of whether the meter is powered or not.

NOTE: When unpowered, your meter's analog inputs act like they are in voltage mode (high input resistance).

When connected to a current output transducer, this high resistance can create a high voltage. Standard (i.e., 4 to 20 mA) current transducers have open circuit protection and are able to handle a high input resistance; however, if non-standard transducers are used high voltages may be generated. Your meter's analog input has circuitry to limit this voltage, but it may not be sufficient with a very high-power current source.

NOTICE

EQUIPMENT DAMAGE

- Ensure the analog input is configured for the correct voltage or current mode before connecting or activating the current transducer.
- Do not exceed the device's ratings for maximum limits.

Failure to follow these instructions will result in equipment damage.

Related topics

- See "Option modules" on page 184 for your option module's analog voltage and current range specifications.

Analog input behavior

Analog inputs may show a value below zero scale if an open circuit is detected on the input port.

Analog output behavior

Your meter's analog output, once configured, outputs voltage or current signals. If your meter's analog output source becomes unavailable (N/A) the analog output level should go to zero (0 V / 0 mA) under most conditions.

When your meter is powered off or configured to send voltage, the meter registers as a high impedance.

The electrical signal on the analog output is DC; make sure proper polarity is observed when wiring external devices to the analog output ports.

An unexpected change of state of the analog outputs can result when the supply power to the meter is interrupted, during an upgrade of the meter's firmware or framework or option module firmware or a during an option module reset.

⚠ WARNING

UNINTENDED OPERATION

Do not use this meter for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Related topics

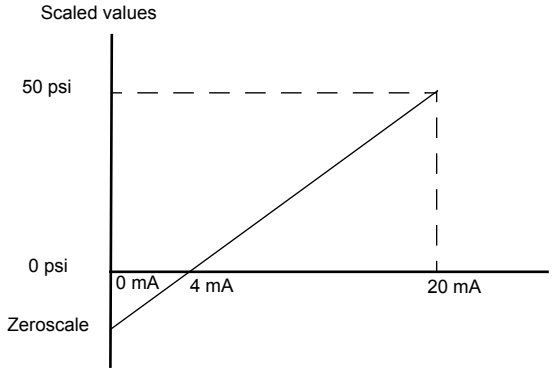
How to calculate analog I/O zero scale and full scale values

Your meter receives an analog signal through its analog input port and scales it before displaying or logging the value. Your meter can also output a scaled analog signal based on measured values such as power. You must calculate the zero scale and full scale values to help ensure the scaled values are correctly interpreted.

Analog inputs will show a value below zero scale if an open circuit is detected on the input port.

The relationship between the analog source range, the zero and full scale values, and the final value provided by your meter, is as follows:

$$\frac{Af - Aa}{Af - Ax} = \frac{Fullscale - X}{Fullscale - Zeroscale}$$



Solving for Zeroscale:

$$Zeroscale = Fullscale - \frac{Fullscale - X}{Af - Aa}(Af - Ax)$$

- Aa = the lowest reading in the nominal operating range that is measured by the meter’s analog input port or produced by the meter’s analog output port
- Af = the highest reading in the nominal operating range that is measured by the meter’s analog input port or produced by the meter’s analog output port
- Ax = the analog input source minimum value or the external analog receiver’s minimum value
- X = the scaled equivalent of Ax

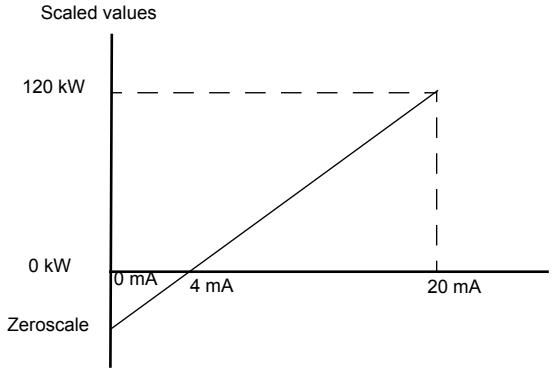
Example (analog input)

The meter's analog input port can measure from 4 - 20 mA, and you need to monitor a steam pressure sensor which measures between 0 - 50 psi of steam. The steam pressure sensor's output ranges from 4 - 20 mA.

$$Zeroscale = Fullscale - \frac{Fullscale - X}{Af - Aa}(Af - Ax)$$

$$Zeroscale = 50 - \frac{50 - 0}{20 - 4}(20 - 0)$$

$$Zeroscale = 50 - 62.5 = -12.5 \text{ psi}$$



- Af = 20 mA
- Aa = 4 mA
- Ax = 0 mA
- Fullscale = 50 psi

Calculating the Zeroscale value from the equation above gives -12.5 psi.

Configuring the meter's analog input with Fullscale = 50 psi and Zeroscale = -12.5 psi produces an output value ranging from 0 - 50 psi represented by a 4 - 20 mA signal.

Example (analog output)

The meter is monitoring a 0 to 120 kW system and outputs the real power over a 4 to 20 mA analog output. The receiving device is expecting the 0 to 120 kW signal to be represented by the 4 to 20 mA signal.

$$Zeroscale = Fullscale - \frac{Fullscale - X}{Af - Aa}(Af - Ax)$$

$$Zeroscale = 120 - \frac{120 - 0}{20 - 4}(20 - 0)$$

$$Zeroscale = 120 - 150 = -30 \text{ kW}$$

- Af = 20 mA
- Aa = 4 mA
- Ax = 0 mA
- Fullscale = 120 kW
- X = 0 kW

Calculating the Zeroscale value from the equation above gives -30 kW.

Configuring the meter's analog output with Fullscale = 120 kW and Zeroscale = -30 kW produces an output value ranging from 0 - 120 kW represented by a 4 - 20 mA signal.

Digital inputs/outputs

Your meter has three digital inputs and one digital output, and you can add digital I/O option modules to increase your meter's capabilities.

Digital I/O allows the meter to send and receive digital signals, including sending energy pulse information that can be used for verifying accuracy or receiving IRIG-B information for time synchronization. You can view the digital I/O values from your meter's display or webpages.

For high-accuracy applications like IRIG-B time synchronization or verifying accuracy, use the meter's onboard digital I/O.

Your meter's digital inputs can be used for input metering and incremental energy applications.

An unexpected change of state of the digital outputs can result when the supply power to the meter is interrupted, during an upgrade of the meter's firmware or framework or option module firmware or a during an option module reset.

⚠ WARNING

UNINTENDED OPERATION

Do not use this meter for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Energy pulsing overview

You can use your meter's digital output or energy pulsing LEDs for energy pulsing.

Energy pulsing is when the meter sends a readable pulse or signal based on the measured energy. This pulse can be used for accuracy verification or as an input to another energy monitoring system. You must calculate your pulse values as either pulses per kWh or as kWh per pulse, as defined by your meter, and set the energy value as active, reactive, or apparent delivered, received, or delivered plus received.

For applications where energy pulsing accuracy is required, use the meter's onboard digital output.

Related topics

- See “Verifying accuracy” on page 175 for instructions on how to perform accuracy verification testing on your meter.
- See the *ION Reference*, available from www.schneider-electric.com, for more information about Calibration Pulser and Pulser modules.

Calculate your maximum kWh/pulse (pulse weight) value

To calculate the kWh/pulse (pulse weight) value, divide the highest kW value you can expect by the required pulse rate. Make sure the required pulse rate does not exceed the maximum pulse rate for the digital output.

NOTE: To convert from kWh/pulse to pulse/kWh you must invert (take the reciprocal) of the value. For example, 1.8 kWh/pulse becomes 0.556 pulse/kWh.

Example

For a maximum load of 1600 kW and a pulse rate of 2 pulses per second, calculate the kWh/pulse value as follows:

1. Convert 1600 kW load into kWh/second:

   (1600 kW)*(1hr) = 1600 kWh

   (1600 kWh)/(3600 sec) = (X kWh)/(1sec)

   X = 0.444 kWh/sec

2. Calculate the kWh required per pulse:

   (0.444 kWh/sec)/(2 pulses per second) = 0.222 kWh/pulse

3. Adjust for the KY giving one pulse per 2 transitions if necessary.

   (0.222 kWh/pulse)/(2) = 0.111 kWh/pulse

Chapter 17 Alarms and alerts

Your meter can display various alarms through the display, and can be configured to send an alert.

⚠ WARNING

INACCURATE DATA RESULTS

Confirm your alarm is properly configured.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Alarms overview

An alarm is a notification of a specific event that is annunciated through the display, and can be viewed and acknowledged using your meter's display.

You can configure your meter to generate and display alarms when predefined events are detected in the meter's measured values or operating states. Your meter also records and stores meter events in the meter's onboard event log.

Your meter comes with many alarms. Some are preconfigured, while others need to be configured before your meter can generate alarms. Your meter's default alarms can be customized, as needed, such as changing the priority. You can create custom alarms using the advanced features of your meter.

NOTE: To stop an alarm from being displayed without impacting other metering features, set its alarm priority to info only.

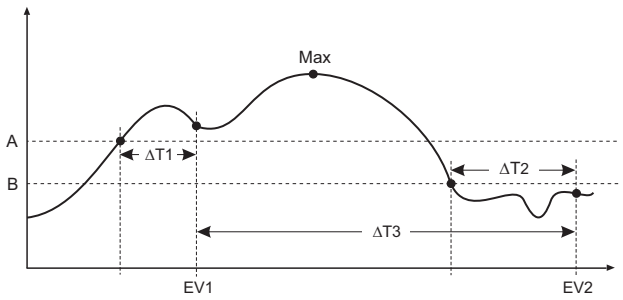
- See the *ION Reference,* available from www.schneider-electric.com, for more information about the Setpoint module.

Alarm types

Your meter has the following types of alarms:

Type	Description
Setpoint (standard)	Setpoint alarms define an alarm by comparing the actual value of a parameter to a specified limit or range of values. These include measured voltage and current values and calculated power quality values. Some setpoint alarms use high-speed measurements for up to 1 millisecond resolution.
Digital	Digital alarms define an alarm condition based on a digital input's on/off state.
Disturbance (sag/swell)	Disturbance alarms define an alarm based on a measured sag or swell.
Unary	Unary alarms are not configurable, and generate an alarm based on the meter's state, for example, the meter powering up.

Alarms have two states:



- Active: the meter detects the alarm condition is met.
- Historical: the alarm condition previously existed but the condition has since returned to a non-alarm state.

Setpoint (standard) alarms

You must define the pickup, dropout and set the time delay for these alarms. You can define the pickup and dropout values as actual values, or as a percentage of the nominal value, and set the time delay to minimize nuisance alarms.

The setpoint alarms operate as either over or under alarms, or as bounding alarms (both over and under values are alarmed).

Example of over setpoint alarm operation

A	Pickup
B	Dropout
ΔT1	Pickup time delay
ΔT2	Dropout time delay
ΔT3	Alarm duration
EV1	Start of alarm
MAX	Maximum value for alarm
EV2	End of alarm

When the monitored value rises above the pickup (A) and remains there long enough to satisfy the pickup time delay period (ΔT1), the setpoint alarm is active. When the value falls below the dropout (B) and remains there long enough to satisfy the dropout time delay period (ΔT2), the alarm is no longer active and becomes a historic alarm.

The meter records the date and time when the alarm event starts (EV1) and when it ends (EV2). The meter records the maximum value (Max) during the alarm period.

Disturbance (sag/swell) alarms

You must configure nominal voltage and current for these alarms to function. For voltage disturbances, enter the percentage deviation from the nominal that defines a sag or swell. For current disturbances, enter the percentage deviation from the nominal that defines the pickup and dropout points for a current sag or a current swell.

Digital alarms

These alarms are triggered when the associated digital input changes state. You can configure the alarm to be active when the digital input is on or off, depending on the alarm's purpose.

For example, if you used a digital input to monitor a breaker that is always supposed to be on, you would set the alarm to be active when the breaker has tripped.

NOTE: To stop a digital alarm from being displayed, set the alarm priority to info only. Disabling (force off) the digital alarm off will disable all functions of the associated digital input.

Alarm event priorities

Your meter's alarm priorities correspond to the following event priority ranges:

Alarm priority	Event priority
High (red)	192 - 255
Medium (yellow)	128 - 191
Low (blue)	64 - 127
Info only (no alarm)[1]	1 - 63
None (no alarm or event)[1]	0

[1] Alarms with priority of info only or none are not indicated or displayed.

Info only and none event priority

Alarms with a priority of info only or none are not shown on the meter's display, and do not function as alarms. If the alarm's priority is set to info only, and the event priority is greater than the event log cutoff value, the associated event is recorded in the meter's event log. If the alarm's priority is set to none, the event priority is automatically set to zero, and no associated event is logged in the meter's event log.

For events that you want to log for future reference or troubleshooting, but don't want alarm functions, set the alarm priority to info only.

For nuisance events that frequently occur and you have no desire to log for reference or troubleshooting, set the alarm priority to none.

Related topics

- See "Event log overview" on page 134 for more information about event priority and the meter's event log.

Alarm indicators

Your meter's display has an alarm indicator to show you what alarm levels have been detected (active or historic) and whether they have been acknowledged. For active high priority alarms, the meter's display will also flash until the alarm is acknowledged. There is also an alarm LED to indicate the meter's alarm condition.

Alarm	Alarm icon	Alarm icon flash	Alarm LED	Meter display
Active high	Red solid bell	Flash if not acknowledged	• Flash if not acknowledged • Steady if acknowledged	Flash if not acknowledged
Active medium	Yellow solid bell	Flash if not acknowledged	• Flash if not acknowledged • Steady if acknowledged	No flash
Active low	Blue solid bell	Flash if not acknowledged	• Flash if not acknowledged • Steady if acknowledged	No flash
Historic high	Red outline bell	Flash if not acknowledged	• Flash if not acknowledged • Steady if acknowledged	No flash
Historic medium	Yellow outline bell	Flash if not acknowledged	• Flash if not acknowledged • Steady if acknowledged	No flash
Historic low	Blue outline bell	Flash if not acknowledged	• Flash if not acknowledged • Steady if acknowledged	No flash

Alarm	Alarm icon	Alarm icon flash	Alarm LED	Meter display
No active or unacknowledged alarms	Gray solid bell	No flash	Off	No flash

If there are multiple active alarms, the meter displays the alarm condition associated with the most important active alarm. If there are multiple unacknowledged historic alarms, the meter displays the alarm condition associated with the most important unacknowledged historic alarm.

NOTE: To stop an alarm from being displayed without impacting other metering features, set the alarm priority to info only.

Default alarms

Your meter comes with the following default alarms.

NOTE: Some alarms require configuration in order to operate.

Name	Priority	Description
Current Sag Ph1 - 3	High	Current sag alarms for phase 1, 2, 3
Current Swell Ph1 - 3	High	Current swell alarms for phase 1, 2, 3
Sag/Swell	High	Voltage sag/swell alarm
Over I unbal	Medium	Over unbalanced current alarm
Over V unbal	Medium	Over unbalanced voltage alarm
Over THD V1 - 3	Medium	Over total harmonic distortion (THD) voltage alarms
Over kW (P) sd	Medium	Over kW sliding demand alarm
Over I a - c, (1 -3) 4	Medium	Over current alarms
V1 - V3 Setpoint	Medium	Voltage setpoint alarms
Freq Setpoint	Medium	Frequency setpoint alarm
4-30 Volt Intrp Ph1 - 3	Low	4-30 voltage interruption power quality alarms
Digital In	Info only	Digital input alarms Number of alarms determined by the total number of available digital inputs **NOTE:** These alarms are not displayed by default.

Alarm information

You can view the following information about an alarm from your meter's display. Only alarms with a priority of low, medium or high are displayed.

Parameter	Description
Alarm	The name of the alarm (for example, Over THD V1).
Priority	Low, medium or high alarm priority.
Date	The date and time the alarm was triggered.
Duration	The duration of the alarm (only applies to inactive alarms).
Ack	The date and time when the alarm was acknowledged (only applies to acknowledged alarms).
Value	Active alarm: The maximum value detected when the alarm was triggered. Historic alarm: The maximum value detected during the duration of the alarm.

Disabling alarms through your meter's display

You can disable alarms through the meter's display when you are performing maintenance tasks on your system and want to prevent nuisance alarms.

NOTE: To stop an alarm from being displayed without impacting other metering features, set the alarm priority to info only.

⚠ WARNING

INACCURATE DATA RESULTS

Confirm your alarm is properly configured.

Failure to follow these instructions can result in death, serious injury or equipment damage.

1. Navigate to **Setup Menu > Alarm Setup**. Press the edit button to access the enable/disable screen. Use the up and down arrows to scroll through the available alarms. Simultaneously press the up and down arrow to enable or disable the highlighted alarm.
2. Press the select button to confirm your settings.
3. Complete the system maintenance tasks.
4. Enable the alarms you disabled in step 1.

Alerting

An alert is an external notification produced by the meter to indicate changes, for example, a change of state for a digital input, or a power quality event such as a sag or swell.

Alerts are generated when a pulse or trigger that is configured to indicate the alert condition activates. You can configure alerts to send notification emails or messages to your energy management system through your meter’s existing Ethernet communications connections. You can configure alert messages as a simple text string or you can also include device information. You can configure the alert’s priority so that alerts are also recorded in the meter’s event log.

You can configure multiple alerts on a single meter, each having different activation triggers, messages and/or transmission types. For instance, you can have two alerts, one generating an email, the other sending a message to your energy management system, but using the same trigger conditions; or you can have two alerts with different conditions that send two unique emails to two different email addresses. You can also generate alerts based on triggers from devices connected to your meter.

Creating alerts is an advanced feature that requires familiarity with ION architecture and your power system and communications network. To create an alert, you must configure the Alert module using a configuration tool. You must also configure your device’s communications as needed to send the alerts, such as configuring your meter’s SMTP settings and connecting it via Ethernet to an SMTP mail server in order to send an alert by email.

Chapter 18 Resets

Resets overview

Resets allow you to clear various accumulated parameters stored on your meter or re-initialize meter accessories.

Meter resets clear your meter's onboard data logs and other related information. Resets are typically performed after you make changes to the meter's basic setup parameters (such as PT/CT settings) to clear obsolete or invalid data in preparation for putting the meter into active service.

You must enter a valid password in order to perform a reset.

NOTE: Revenue-locked meters must be unlocked to perform meter resets that affect revenue data.

Related topics

- See "Revenue locking" on page 173 for more information locking and unlocking revenue locked meters.

Meter resets

You can perform various meter resets through the meter's display or ION Setup.

Your meter's digital and analog outputs may change state or may not function during resets.

⚠ WARNING

HAZARD OF UNINTENDED OPERATION

Do not use the meter for critical control or protection applications where human or equipment safety relies on the operation of the control circuit.

Failure to follow these instructions can result in death, serious injury or equipment damage.

Meter resets clear the meter's onboard data logs and other related information.

NOTICE

DATA LOSS

Ensure all important data from the device has been retrieved before performing a reset.

Failure to follow these instructions can result in data loss.

Reset	Description
Master Reset	• Clears all the cumulative and derived quantities from the meter (including demand, peak demand, energy and revenue parameters). • Clears meter event and waveform logs. • Clears COMTRADE waveform records from the meter's internal FTP server. • Clears the meter's data logs.
Peak Demand Reset	Clears the peak demand values logged in the meter. **NOTE:** The peak demand reset has a lockout period that sets the minimum time allowed between consecutive resets.
Min/Max Reset	Clears all accumulated maximum and minimum values stored in the meter.
Digital Input Count Reset	Clears the digital input status change counters.
Harmonics Min/Max Reset	Clears all accumulated maximum and minimum harmonics values stored in the meter.
Disturbance Count Reset	Clears the sag/swell event counter. The sag/swell event counter counts the number of sag/swells that have occurred since power-up or the last reset, to provide power quality information to energy management systems.
EN50160 Reset	Clears all EN50160 parameters and statistics accumulated in the meter.
Option modules reset	Resets communications to the meter's expansion modules.
Conditional energy reset[1]	Clears the conditional energy values stored in the meter.
Input metering reset[1]	Clears the input metering values stored in the meter.

[1] These resets are only available through ION Setup.

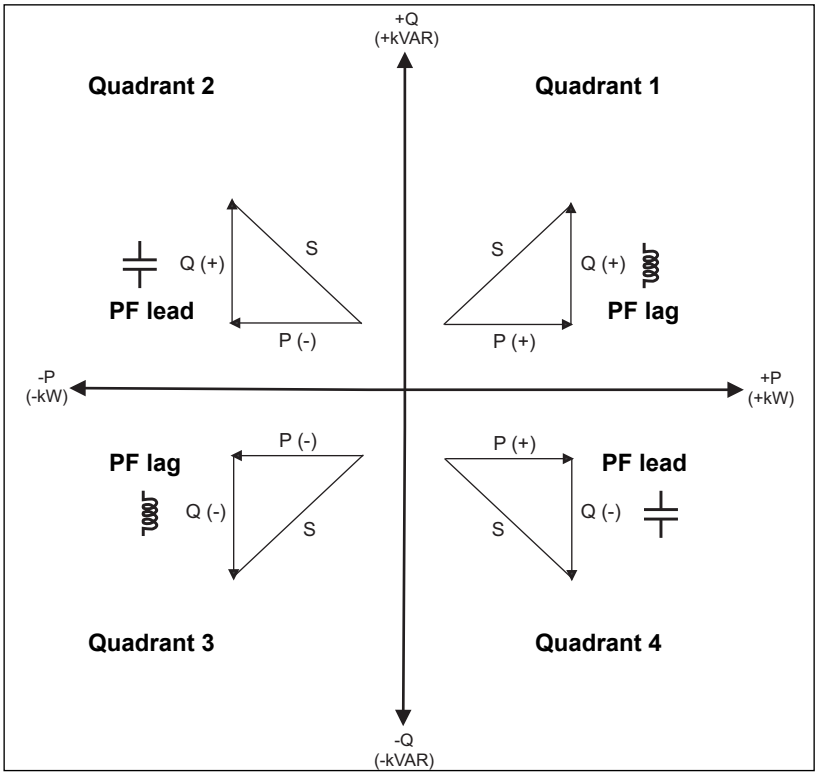
Chapter 19 Power and power factor

This section describes how the meter interprets and calculates power and power factor.

NOTE: The descriptions in this section assume that you are an electrical energy consumer, not a supplier.

Power and power factor conventions

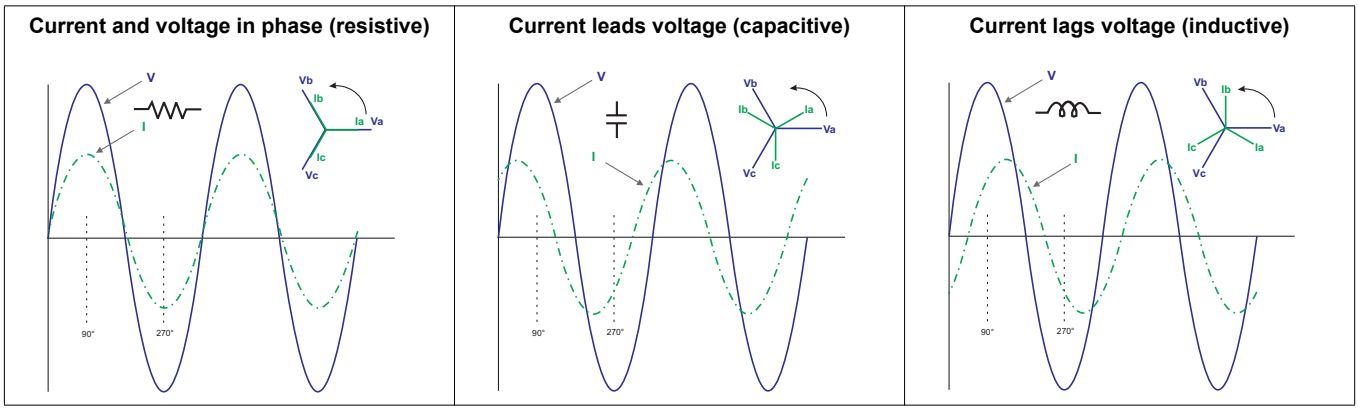


Values for power and power factor are interpreted according to the conventions shown in the diagram below.

Apparent, active and reactive power (PQS)

A typical AC electrical system load has both resistive and reactive (inductive or capacitive) components. Resistive loads consume real power (P). Reactive power (Q) is either consumed (inductive loads) or generated (capacitive loads).

Apparent power (S) is the capacity of your measured power system to provide real and reactive power.



The units for power are watts (W or kW) for real power P, vars (VAR or kVAR) for reactive power Q, and volt-amps (VA or kVA) for apparent power S.

Positive real power P(+) flows from source to load, and negative real power P(-) flows from the load to the power source.

Current phase shift from voltage

For purely resistive loads, the current waveform is in phase with the voltage waveform. For capacitive loads, current leads voltage. For inductive loads, current lags voltage. The following diagram shows how voltage and current waveforms shift based on load type under ideal (laboratory) conditions.

Current lead / lag and load type

Power factor (PF)

Power factor (PF) is the ratio of real power (P) to apparent power (S) and is provided as a number between -1 and 1 or as a percentage from -100% to 100%, where the sign is determined by convention.

$$PF = \frac{P}{S}$$

An ideal, purely resistive load has no reactive components, so its power factor is one (PF = 1, or unity power factor). Inductive or capacitive loads introduce a reactive power (Q) component to the circuit which causes the PF to become closer to zero.

Related topic

- See “Power and power factor conventions” on page 157 for power factor sign convention information.

True PF and displacement PF

The meter supports true power factor and displacement power factor values:

- True power factor includes harmonic content.
- Displacement power factor only considers the fundamental frequency.

NOTE: Unless specified, the power factor displayed by the meter is true power factor.

PF min/max convention

The meter uses the following convention for power factor minimums and maximums.

For negative PF readings:

- The minimum PF value is the measurement closest to -0.
- The maximum PF value is the measurement closest to -1.

For positive PF readings:

- The maximum PF value is the measurement closest to +1.
- The minimum PF value is the measurement closest to +0.

Chapter 20 Power quality

Your meter measures voltage and current harmonics up to the 63rd harmonic, and calculates several harmonic distortion values as well as K-factor and crest factor values.

You must configure your meter with nominal values for voltage, current and frequency for the power system being monitored in order for the meter to perform power quality calculations. Your meter also creates a phasor diagram, including numeric values for magnitude and angle, to represent your power system.

- See the *4-30 compliance and ION meters* technical note, available from www.schneider-electric.com, for details on how your meter complies with the 4-30 standard.

Sag/swell overview

Your meter monitors your power system’s voltage and current for sags and swells (INCITS (CBEMA) Type 2 and Type 3 disturbances); it then reports the disturbance’s magnitude and duration.

You can manually enter the limits (criteria) used by the meter to identify a sag or swell, or you can have your meter learn sag/swell limits by monitoring your power system.

- See “Waveform recording overview” on page 135 for details on how your meter records voltage and current waveform information.

Harmonics overview

Voltage and current harmonics are measured or calculated by your device, for use in standards compliance and power quality analysis.

Harmonics are integer multiples of the fundamental frequency of your monitored power system. Harmonics information is valuable for power quality analysis, determining properly rated transformers, maintenance and troubleshooting, and is required for compliance to system power quality standards such as EN50160 and meter power quality standards such as IEC 61000-4-30.

Harmonics measurements include per-phase magnitudes and angles (relative to the fundamental frequency of the phase A voltage) for the fundamental and higher harmonics. The device's power system configuration determines which phases are present, and how line-to-line or line-to-neutral voltage harmonics and current harmonics are calculated.

Harmonics are used to identify whether the supplied system power meets required power quality standards, or if non-linear loads are affecting your power system. Power system harmonics can cause current flow on the neutral conductor, and damage to equipment such as increased heating in electric motors. Power conditioners or harmonic filters can be used to minimize unwanted harmonics.

Your meter provides harmonic information up to the 63rd harmonic. Harmonic information can be viewed on the meter's display, and is recorded by your meter.

- See "Default data logging configuration" on page 131 for information on how harmonic information is logged on your meter.

Crest factor and K-factor overview

Crest factor is the ratio of peak to RMS values, and is available for both voltage and current. For a pure sinusoidal waveform, crest factor is equal to the square root of 2. The meter uses the following equation to calculate crest factor:

$$\text{Crest factor} = \frac{V_{peak}}{V_{RMS}}$$

$$\text{Crest factor} = \frac{I_{peak}}{I_{RMS}}$$

K-factor relates to the heating effect of a distorted current in a transformer to a sinusoidal current with the same RMS magnitude: it describes a transformer's ability to serve non-linear loads with out exceeding rated temperature rise limits. The K-factor is equal to the sum of the squares of the harmonic currents multiplied by the squares of the harmonic order. The meter uses the following equation to calculate K-factor:

$$\text{K-factor} = \frac{\sum_{h=1}^{63} (I_h^2 \times h^2)}{\sum_{h=1}^{63} (I_h^2)}$$

Where "h" is the harmonic order and "I_h" is the RMS current of harmonic order "h".

Related topics

- See the *ION Reference,* available from www.schneider-electric.com, for details about the Harmonics Measurement module.
- See "Harmonics logs" on page 132 for information on how K-factor information is logged on your meter.

Total harmonic distortion overview

Total Harmonic Distortion (THD) is a measure of the total per-phase voltage or current harmonic distortion present in the power system. It provides a general indication of the quality of a waveform. THD is calculated for each phase of both voltage and current.

The meter uses the following series of equations to calculate THD.

Harmonic content calculations

Harmonic content (H_C) is equal to the RMS value of all the non-fundamental harmonic components in one phase of the power system, and this value is used in THD calculations. The meter uses the following equation to calculate H_C:

$$H_C = \sqrt{(H_2)^2 + (H_3)^2 + (H_4)^2 \ldots}$$

THD calculations

THD is a quick measure of the total distortion present in a waveform and is the ratio of harmonic content (H_C) to the fundamental harmonic (H_1). The meter uses the following equation to calculate THD:

$$THD = \frac{H_C}{H_1} x 100 percent$$

thd and TDD

Your meter can be configured to provide thd (total harmonic distortion using the total RMS value for the content rather than the fundamental content) and TDD (total demand distortion, the harmonic current distortion against the maximum demand of the electrical system.

$$thd = \frac{H_C}{RMS} x 100 percent$$

$$TDD = \frac{H_C}{Demand_{Max}} x 100 percent$$

This is an advanced procedure that should only be performed by users with an advanced knowledge of power quality, ION architecture, and the power system being monitored.

- See “Viewing data using your meter’s display” on page 30 for information on how to view total harmonic distortion values on your meter’s display.

Phasor overview

Phasors are used to represent the voltage and current relative magnitude and angles. They can be viewed through your meter’s display or webpages.

The length of the lines in the phasor diagram represent the relative magnitude of the voltages with respect to the other phase voltages, and the currents with respect to the other phase currents. All angles are measured with respect to the Va/V1 phase. The Va/V1 phasor is fixed to the right-hand horizontal axis (positive x-axis). Positive angles are measured counterclockwise.

Numeric values are provided for the magnitude and relative angle for each voltage and current phase.

Phasor information can be used to troubleshoot incorrect connections on the meter's voltage and current inputs, if you know how the phasors should be oriented for your power system.

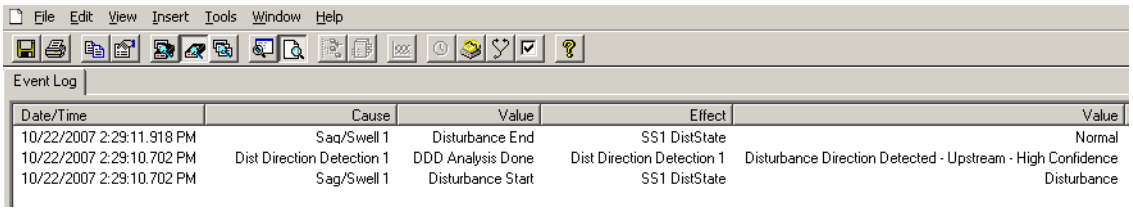
Disturbance direction detection overview

Your meter has disturbance direction detection capabilities to help you determine the location of a power system disturbance. When a disturbance occurs, the meter analyzes the disturbance information to determine the direction of the disturbance relative to the meter. This analysis includes a confidence level indicating the level of certainty that the disturbance is in the determined direction, and is stored in your meter's event log.

Disturbance direction detection is enabled on your meter by default and does not require any additional configuration beyond setting the nominal voltage and nominal frequency.

Disturbance direction detection can help locate the source of a disturbance when used in a system of disturbance direction detection devices, as shown in the diagram below.



A	Disturbance location
B	Meter #1 reports downstream disturbance
C	Meter #2 reports upstream disturbance
D	Meters report upstream disturbance
E	Meter reports downstream disturbance

The arrows show the direction the meters have determined for the disturbance. With this information, you can determine that the disturbance occurred between meter #1 and meter #2, and can focus on that section of your system to find the cause of the disturbance.

Viewing disturbance direction detection events

The results of the disturbance direction detection algorithm appear in the meter's event log. The image below shows an example of how the Disturbance Direction Detection event appears in your meter's event log when viewed using ION Setup.

NOTE: You can view your meter's event log through the display and ION Setup.

Date/Time	Cause	Value	Effect	Value
10/22/2007 2:29:11.918 PM	Sag/Swell 1	Disturbance End	SS1 DistState	Normal
10/22/2007 2:29:10.702 PM	Dist Direction Detection 1	DDD Analysis Done	Dist Direction Detection 1	Disturbance Direction Detected - Upstream - High Confidence

Chapter 21 Energy and demand

This section includes information on the energy monitoring features of your meter, conditional energy and WAGES (water, air, gas, electricity, steam) input metering. It also provides information on the different power demand calculation methods you can configure on your meter.

Conditional energy

Conditional energy allows you to define an accumulation period for real and reactive energy using one of your meter's digital inputs.

You can use conditional energy to track four-quadrant accumulated energy during a specific period; for example you may want to track accumulated energy values during a particular process controlled using a programmable logic controller (PLC).

Conditional energy is accumulated until it is reset. The conditional energy reset date and time information is stored in the meter's event log.

Related topics

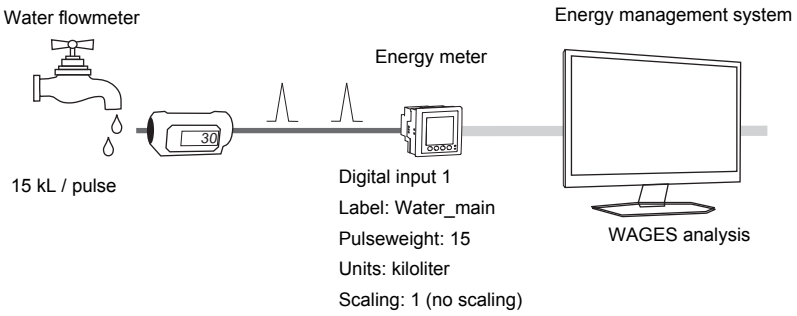
- See "Configuring conditional energy using ION Setup" on page 98 for instructions on how to enable and trigger conditional energy accumulation.
- See "Power and power factor conventions" on page 157 for a detailed description of four-quadrant energy values.

WAGES monitoring overview

Water, air, gas, electric and steam (WAGES) monitoring allows you to monitor and analyze of your energy system's energy sources and utilities usage.

Your meter's digital inputs can be used to count pulses from transducers and convert the pulses to energy measurements for WAGES applications.

This can help you:



- Identify losses or inefficiencies.
- Modify demand to reduce costs.
- Optimize energy source usage.

Your energy system may use several different types of energy. You may consume steam or compressed air for industrial processes, electricity for lights and computers, water for cooling and natural gas for heating. WAGES collects the usage information from all these different energy sources for a more complete energy analysis.

WAGES example

You can connect your meter's digital input to a transducer that sends a pulse for every 15 kiloliters (4000 US Gal) of water. This information is then labeled, scaled, given a

unit of measure and logged in the meter's onboard memory for subsequent loading into your energy management system.

Related topics

- See "Input metering overview" on page 168 for a description of how your meter supports WAGES information.

Input metering overview

Your meter's digital inputs can be used to count pulses from transducers and convert the pulses to energy measurements for WAGES applications.

Your meter's input metering channels count pulses received from the digital inputs assigned to each channel. The incoming pulses are used in calculating and measuring consumption data (e.g. BTU, kWh, L, kg). Each channel must have the following values configured to match the pulse data:

- Pulse weight: the value per pulse.
- Units: the unit of measure associated with the metered quantity.
- Rate: the time base associated with input metering accumulations. For units with a defined rate, this value is used for scaling.
- Demand period: how frequently the input metering data is calculated in your energy management system.

You can use standard units and rates to configure input metering, or you can create custom input metering parameters for specialized applications.

Standard input metering example

Your meter's onboard digital input S1 is monitoring a flow meter (identified as FL3) that sends one pulse for every 100 liters of water. Your energy management system has a demand period of 15 minutes, and calculates the input metering data using an hourly rate.

Parameter	Value
Assigned Input	S1
Standard quantity	Selected
Pulse Weight	100
Units	L
Rate	l/hr
Demand period	15 minutes
Source ID	FL3

Custom input metering example

Your meter's onboard digital input S1 is monitoring a flowmeter (BF5) installed inside bottle-filling equipment. The desired measurement quantity is bottles/shift (numbers of bottles filled during an eight-hour shift). Each bottle takes 0.4 liters of liquid, and the flowmeter pulses once for every 100 liters. Your energy management system has a demand period of 15 minutes, and calculates the input metering data using an hourly rate.

Pulse weight calculation:

$$\frac{100 \text{ (liters/pulse)}}{0.4 \text{ (liters/bottle)}} = 250 \text{ (bottles/pulse)}$$

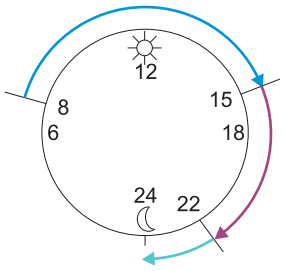
Parameter	Value
Assigned Input	S1
Standard quantity	Cleared
Pulse Weight	250
Units	Bottles@BF5
Rate	Bottles/shift
Demand period	15 minutes
Scaling	1
Time Base	8 hours

Incremental energy

Incremental energy allows you to define a start time, end time, and the time interval (increments) for incremental energy accumulation. At the end of each interval, the energy accumulated during that period is stored. By default, the meter only records the previous interval's incremental energy and the instantaneous energy accumulations in the active interval.

The first interval of incremental energy accumulation begins at the specified start time. Incremental energy ends at the specified end time, which may result in a truncated interval if the interval duration does not divide evenly into the overall incremental energy duration (for example, an interval duration of three hours with an overall duration of five hours truncates the last interval duration to two hours). The latest value for the specified end time is midnight (24:00).

Your start time must be before the end time and after midnight, and the period over which incremental energy is accumulated cannot include midnight. This is because your meter's start and end times are defined relative to midnight.



Start: 6am, End: 12am, interval: 3hrs	Incremental energy accumulates from 6am to midnight in intervals of 3 hours.
Start: 6am, End: 2am, interval: 3hrs	Incremental energy will not function. End time must be after start time and before or equal to midnight.

Incremental energy helps provide information for analyzing energy and power usage against present or future utility rates, and is useful for comparing different time-of-use rate structures.

When configuring incremental energy, shorter incremental energy periods provide more granular data which can make the data easier to use for comparison purposes.

Incremental energy example

- Start time: 8 am or 08:00
- End time: 12 am or 24:00
- Interval: 420 minutes (7 hours)

A	First interval (08:00 to 15:00)
B	Second interval (15:00 to 22:00)
C	Third interval (22:00 to 24:00)

The first incremental energy interval is from 8 am (start time) to 3 pm, and is seven hours long. The second incremental energy interval is from 3 pm to 10 pm, and is also seven hours long. The third interval is from 10 pm to 12 am, and is only 2 hours long because 12 am is the specified end time. These intervals repeat every 24 hours until the configuration is changed or incremental energy feature is disabled.

Related topics

- See “Configuring incremental energy using ION Setup” on page 100 for instructions on how to configure your meter’s start and end times and interval values.

Demand

Demand (also referred to as power demand) is a measure of average power consumption over a fixed time interval. Peak (or maximum) demand is the highest demand level recorded over the billing period. Your meter calculates the average current demand and kW, kVAR and kVA demand using sliding window demand methods.

The meter supports coincident demand values when a peak demand is detected.

Your meter’s default configuration is suitable for most applications, or you can customize it for your specific application.

You can configure the minimum time between consecutive demand resets.

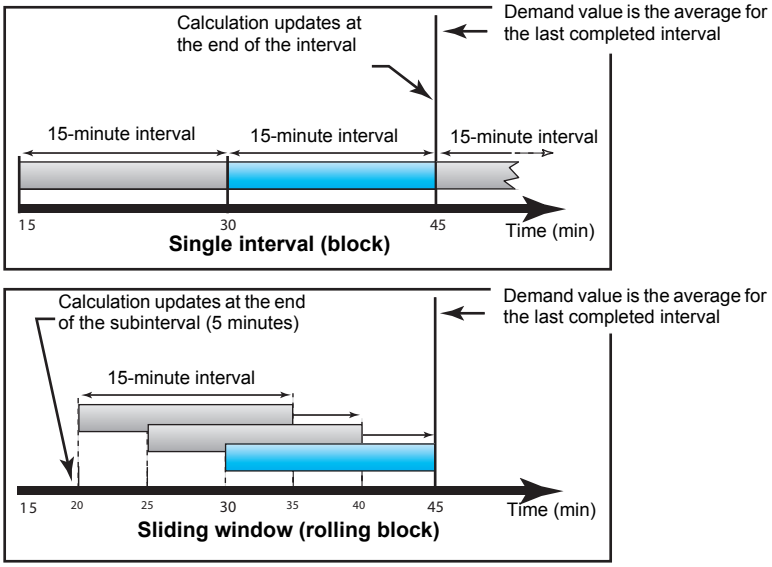
NOTE: If not specified, references to “demand” are assumed to mean “power demand”.

Related topics

- See “Peak demand reset lockout” on page 172 for information about your meter’s peak demand reset lockout feature.
- See the ION Setup online help for instructions on how to configure demand on your meter.
- See the *ION Reference,* available from www.schneider-electric.com, for detailed information on how Sliding Window Demand modules measure and calculate demand values.
- See“Viewing data using your meter’s display” on page 30 for instructions on how to navigate and use your meter’s display.

Sliding window demand

To calculate demand values, your meter uses the sliding window averaging (or rolling interval) method which divides the demand interval into a set number of subintervals of specified duration.



The demand is measured electronically based on the average load level over the most recent set of subintervals.

Sliding window demand also provides predicted demand values.

Examples of sliding window demand

This example shows two different ways of configuring a 15-minute demand interval:

- Single interval (also called block or timed block): the 15-minute demand interval is defined as a single subinterval with a duration of 15 minutes.
- Sliding window (also called rolling block): the 15-minute demand interval is defined as three subintervals with a duration of 5 minutes each. This method offers better response time than a single interval.

Peak demand

Power utilities generally bill commercial customers based on their peak usage levels, called peak demand (in kW) and energy consumption (in kWh). Peak (or maximum) demand is the highest demand level recorded over the billing period. You can view peak demand values on your meter’s display.

Peak demand reset lockout

The demand reset lockout time sets the minimum time allowed between consecutive demand resets; the meter ignores any attempts to reset demand that occur within the lockout period.

The peak demand reset lockout period is user-configurable, with a default value of 25 days.

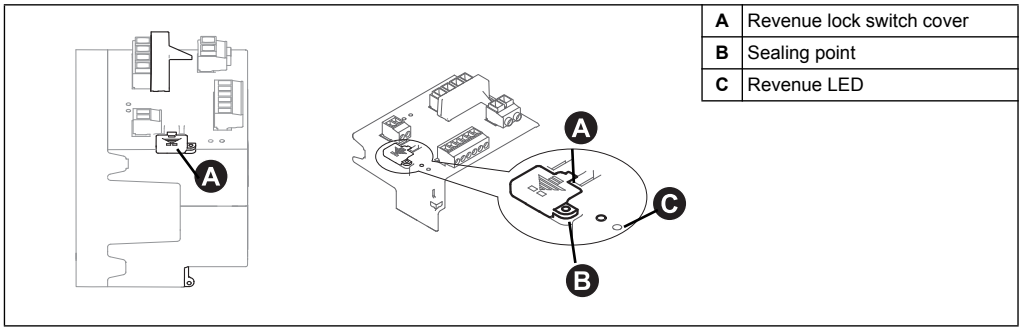
Chapter 22 Revenue

Revenue overview

This section describes your meter's revenue-related features: revenue locking, time of use, PT/CT (potential transformer/current transformer) correction and the recommended process for verifying the accuracy of your meter.

Revenue locking



Revenue locking your meter helps prevent modifications to revenue-related settings and data on your meter, or tampering with your meter's voltage and current connections. Revenue locking may be required to help meet government regulations and utility security requirements, or can be used to help ensure the validity of revenue data.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E in the USA or applicable local standards.
- Turn off all power supplying this device and the equipment in which it is installed before working on the device or equipment.
- Always use a properly rated voltage sensing device to confirm that all power is off.

Failure to follow these instructions will result in death or serious injury.

1. Turn off all power supplying this device and the equipment in which it is installed before working on the device or equipment.
2. Always use a properly rated voltage sensing device to confirm that all power is off.
3. Open the revenue lock switch cover.
4. Locate the revenue lock switch. Click the switch to toggle revenue locking on or off.
5. Close the revenue lock switch cover and make sure it is firmly in place.
6. Seal the revenue lock switch cover if required.

Time of use

Time of use (TOU) is often used when a utility has set up schedules with different rates based on time of day, type of day and date when energy is consumed.

You can view the TOU active rates and seasons through your meter's display.

Related topics

- See "Viewing data using your meter's display" on page 30 for instructions on how to view the TOU active rate and seasons through the meter's display.
- See the ION Setup online help, available from www.schneider-electric.com, for instructions on how to configure time of use on your meter.
- See the *ION Reference,* available from www.schneider-electric.com, for a description of the Time of Use module and its settings.

PT/CT correction

The primary application for PT/CT (potential transformer / current transformer) correction is to apply correction factors for ratio errors and phase angle errors to instrument transformers. PT/CT correction, also called instrument transformer correction, can help reduce the need to replace transformers in installations where high accuracy is required.

PT/CT correction is done for each current and voltage input to the meter and only affects 1-second power meter data and values derived from it, such as energy or demand. No high-speed, harmonics or waveform values are affected by the correction.

NOTE: For those familiar with ION architecture, the relevant 1-second Power Meter module outputs are compensated using the Instr Xformer (ITC) Correction module, and therefore so are all other modules that use that Power Meter module's data.

Related topics

- See the ION Setup online help, available from www.schneider-electric.com, for instructions on how to configure PT/CT correction on your device.

Verifying accuracy

All meters are tested and verified at the factory in accordance with International Electrotechnical Commission (IEC) and American National Standards Institute (ANSI) standards.

Your digital power meter typically does not require re-calibration. However, in some installations, a final accuracy verification of the meter is required, especially if the meter is used for revenue or billing applications.

Testing overview

The most common method for testing meter accuracy is to apply test voltages and currents from a stable power source and compare the meter's readings with readings from a reference device or energy standard.

Accuracy test requirements

Signal and power source

The meter maintains its accuracy during voltage and current signal source variations but its energy pulsing output needs a stable test signal to help produce accurate test pulses. The meter's energy pulsing mechanism needs approximately 10 seconds to stabilize after every source adjustment.

The meter must be connected to control power in order to conduct accuracy verification testing.

Control equipment

Control equipment is required for counting and timing the pulse outputs from the energy pulsing LED or the digital output.

- Most standard test benches have an arm equipped with optical sensors to detect LED pulses (the photodiode circuitry converts detected light into a voltage signal).
- The reference device or energy standard typically has digital inputs that can detect and count pulses coming from an external source (for example, the meter's digital output).

NOTE: The optical sensors on the test bench can be disrupted by strong sources of ambient light (such as camera flashes, florescent tubes, sunlight reflections, floodlights, etc). This can cause test errors. Use a hood, if necessary, to block out ambient light.

Environment

The meter should be tested at the same temperature as the testing equipment. The ideal temperature is about 23 °C (73 °F). Make sure the meter is warmed up sufficiently before testing.

A warm-up time of 30 minutes is recommended before beginning energy accuracy verification testing. At the factory, the meters are warmed up to their typical operating temperature before calibration to help ensure that the meters reach their optimal accuracy at operating temperature.

Most high precision electronic equipment requires a warm up time before it reaches its specified performance levels. Energy meter standards allow the manufacturers to specify meter accuracy derating due to ambient temperature changes and self-heating.

Your meter complies with and meets the requirements of these energy metering standards.

Reference device or energy standard

To help ensure the accuracy of the test, it is recommended that you use a reference device or reference energy standard with a specified accuracy that is 6 to 10 times more accurate than the meter under test. Before you start testing, the reference device or energy standard should be warmed up as recommended by its manufacturer.

Verify the accuracy and precision of all measurement equipment used in accuracy testing (for example, voltmeters, ammeters, power factor meters).

Energy pulsing

Your meter has two energy pulsing LEDs, one visible light and one infrared, located on the meter base. These LEDs emit pulses that are then used to determine the accuracy of the meter's energy measurements. The pulses of light indicate accumulated energy; the meter's accumulations are compared with the reference/standard's accumulated energy in order to help determine the meter's accuracy.

Your meter also has a digital output that can be used for energy pulsing. The relay closes (low impedance) and then opens (high impedance) to represent a pulse. If the accuracy testing equipment has a voltage requirement, a current-limited wetting supply voltage must be provided.

NOTE: Digital outputs on option modules should not be used meter accuracy testing.

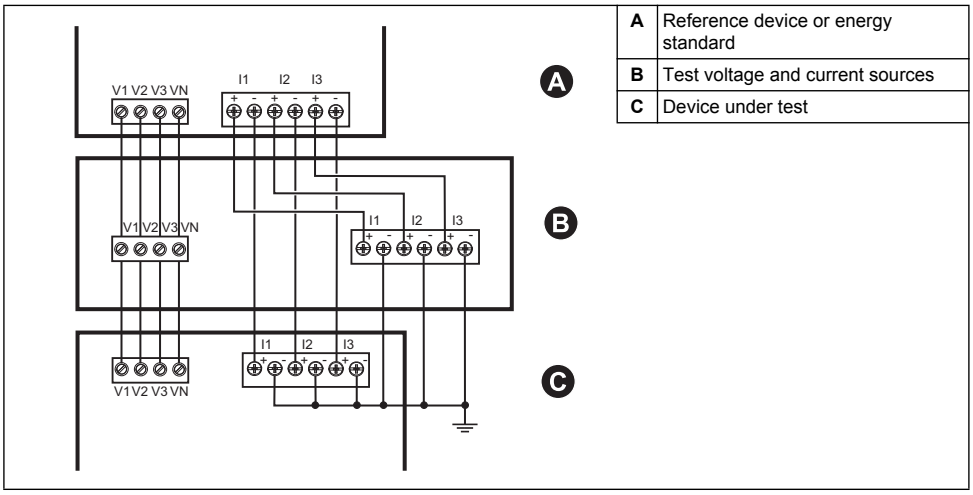
Verifying accuracy test

The following are guidelines for testing the meter; your meter shop may have specific testing methods.



⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E in the USA or applicable local standards.
- Turn off all power supplying this device and the equipment in which it is installed before working on the device or equipment.
- Always use a properly rated voltage sensing device to confirm that all power is off.
- Do not exceed the device's ratings for maximum limits.
- Verify the device's power source meets the specifications for your device's power supply.

Failure to follow these instructions will result in death or serious injury.

1. Turn off all power supplying this device and the equipment in which it is installed before working on the device or equipment.
2. Use a properly rated voltage sensing device to confirm power is off.
3. Connect the test voltage and current source to the reference device or energy standard. Ensure all voltage inputs to the meter under test are connected in parallel and all currents inputs are connected in series.

A	Reference device or energy standard
B	Test voltage and current sources
C	Device under test

4. Connect the control equipment used for counting the standard output pulses using one of these methods:

Energy pulsing LED	Align the red or infrared light sensor on the standard test bench armature over the corresponding energy pulsing LED.
Digital output	Connect the meter's onboard digital output to the standard test bench pulse counting connections.

NOTE: When selecting which method to use, be aware that the energy pulsing LEDs and digital output may have different pulse rate limits.

5. Before performing the verification test, let the test equipment power up the meter and apply voltage for at least 30 seconds. This helps stabilize the internal circuitry of the meter.

6. Set the meter's volts mode to 4W-Wye (4 wire Wye).
7. Disable PT/CT correction unless you want the correction included in the verification test.
8. Depending on the method selected for counting the energy pulses, configure the meter's energy pulsing LEDs or the digital output to perform energy pulsing. Set the meter's energy pulse constant so it is synchronized with the reference test equipment.
9. Perform accuracy verification on the test points. Run each test point for at least 30 seconds to allow the test bench equipment to read an adequate number of pulses. Allow 10 seconds of dwell time between test points.

Related topics

- See "PT/CT correction" on page 174 for details of how PT/CT corrections (also called instrument transformer correction) affects your meter's measurements.

Calculate the number of required pulses

The reference test equipment typically requires you to specify the number of pulses required for a test duration of "t" seconds. Normally, the number of pulses required is at least 25 pulses, and the test duration is greater than 30 seconds.

Use the following formula to calculate the required number of pulses:

$$\text{Number of pulses} = \frac{Ne * V * I * PF * t}{3600 * Kt}$$

Where:

- Ne = number of metering elements used
- V = test point voltage in line-to-neutral volts [V] per phase
- I = test point current in amps [A] per phase
- t = test duration in seconds [s] which must be longer than 30 seconds
- PF = power factor
- Kt = pulse constant programmed in the meter under test in Wh/pulse

Round up the result of the calculation to the nearest integer number of pulses.

Example calculation for number of required pulses

This example calculates the number of pulses required for an inductive load 3-phase test point with a test duration of 60s; the source is configured to use V = 120V, I = 5A, PF = -0.5; the pulse constant of the meter under test is Kt = 1.8 Wh/pulse.

$$8.3 = \frac{3 * 120V * 5A * 0.5 * 60\ s}{3600 * 1.8}$$

Round the number up to the nearest integer: Number of pulses = 9

Calculate the percentage error

For every test point:

$$\text{Energy Error} = \frac{EM - ES}{ES} * 100\%$$

Where:

- EM = energy measured by the meter under test
- ES = energy measured by the reference device or energy standard.

If accuracy verification indicates that there may be inaccuracies with your meter, they may be caused by typical sources of test errors. If there are no sources of test errors present, please contact your local Schneider Electric representative.

Related topics

- See “Typical sources of test errors” on page 179 for possible causes of test errors.
- See “Power factor (PF)” on page 159 for information on how the meter calculates power factor.

Test points

The meter should be tested at full and light loads and at lagging (inductive) power factors to help ensure testing over the entire range of the meter. The test amperage and voltage input rating are labeled on the meter. Refer to the installation sheet or data sheet for your meter’s nominal current, voltage and frequency specifications.

Sample Watt-hour test points

Watt-hour test point	Sample accuracy verification test point
Full load	100% to 200% of the nominal current, 100% of the nominal voltage and nominal frequency at unity power factor or one (1).
Light load	10% of the nominal current, 100% of the nominal voltage and nominal frequency at unity power factor or one (1).
Inductive load (lagging power factor)	100% of the nominal current, 100% of the nominal voltage and nominal frequency at 0.50 lagging power factor (current lagging voltage by 60° phase angle).

Sample Var-hour test points

Var-hour test point	Sample accuracy verification test point
Full load	100% to 200% of the nominal current, 100% of the nominal voltage and nominal frequency at zero power factor (current lagging voltage by 90° phase angle).
Light load	10% of the nominal current, 100% of the nominal voltage and nominal frequency at zero power factor (current lagging voltage by 90° phase angle).
Inductive load (lagging power factor)	100% of the nominal current, 100% of the nominal voltage and nominal frequency at 0.87 lagging power factor (current lagging voltage by 30° phase angle).

Typical sources of test errors

If excessive errors are observed during accuracy testing, examine your test setup and test procedures to eliminate typical sources of measurement errors:

- Loose connections of voltage or current circuits, often caused by worn-out contacts or terminals. Inspect terminals of test equipment, cables, test harness and the meter under test.

- Device ambient temperature is significantly different than 23 °C (73 °F).
- Floating (ungrounded) neutral voltage terminal in any configuration with unbalanced phase voltages.
- Inadequate device control power, resulting in the device resetting during the test procedure.
- Ambient light interference or sensitivity issues with the optical sensor.
- Unstable power source causing energy pulsing fluctuations.
- Incorrect test setup: not all phases connected to the reference device or the energy standard. All phases connected to the device under test should also be connected to the reference meter/standard.
- Moisture (condensing humidity), debris or pollution present in the device under test.

This is the safety alert symbol. It is used to alert you to potential personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates a hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a hazardous situation which, if not avoided, **can result in** minor or moderate injury.

NOTICE

NOTICE is used to address practices not related to physical injury. The safety alert symbol is not used with this signal word.

Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

FCC Notice

This equipment has been tested and found to comply with the limits for a Class A digital device, pursuant to part 15 of the FCC Rules. These limits are designed to provide reasonable protection against harmful interference when the equipment is operated in a commercial environment. This equipment generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with the instruction manual, may cause harmful interference to radio communications. Operation of this equipment in a residential area is likely to cause harmful interference in which case the user will be required to correct the interference at his own expense. This Class A digital apparatus complies with Canadian ICES-003.

Section 1— General Information

Introduction

The Masterpact NW low-voltage power circuit breaker[1] and insulated case circuit breaker are designed to mount in a drawout cradle, using rear-mounted, plug-on pressure connections to provide electrical connection to the cradle. A fixed-mounted circuit breaker is also available.

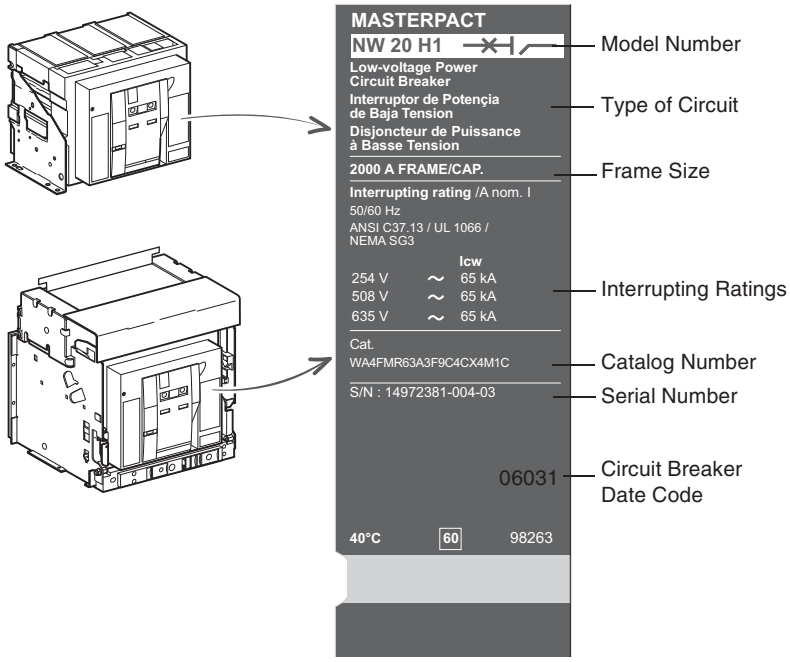
Type L1F 800–2000 A low-voltage power circuit breakers and Type LF 800–2000 A insulated case circuit breakers are tested to show the arc-flash hazard risk category as referenced by NFPA 70E.



This bulletin provides installation instructions for Masterpact NW circuit breakers. Tripping functions are controlled by the Micrologic™ trip unit.

Information about a specific circuit breaker can be found on the faceplate label on the front of the circuit breaker.

Information about the accessories installed in the circuit breaker can be found on the accessory label on the right side of the circuit breaker.

For complete information on available circuit breaker models, frame sizes, interrupting ratings, sensor sizes and trip units, see catalog 0613CT1001, *Masterpact NT and NW Universal Power Circuit Breakers* on the Schneider Electric website.

Before Working on Circuit Breaker

1. Turn circuit breaker off:

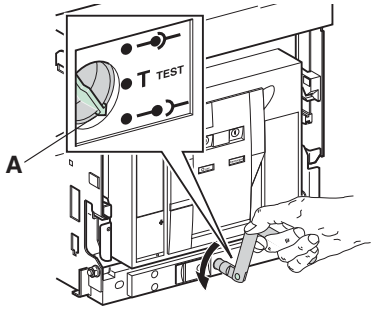
   Press “Push to close” button (**Figure 3, A**) to discharge spring, as indicated by window (**B**).

   Press “Push to open” button (**C**) to open contacts, as indicated by window (**D**).

Figure 3 – Turn Off Circuit Breaker

2. Disconnect power from circuit breaker.

   — For drawout circuit breaker: rack circuit breaker to disconnected position (**Figure 4, A**). See Drawout Circuit Breaker Disconnection, page 70.



⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Beware of potential hazards, wear personal protective equipment and take adequate safety precautions.

Failure to follow these instructions will result in death or serious injury.

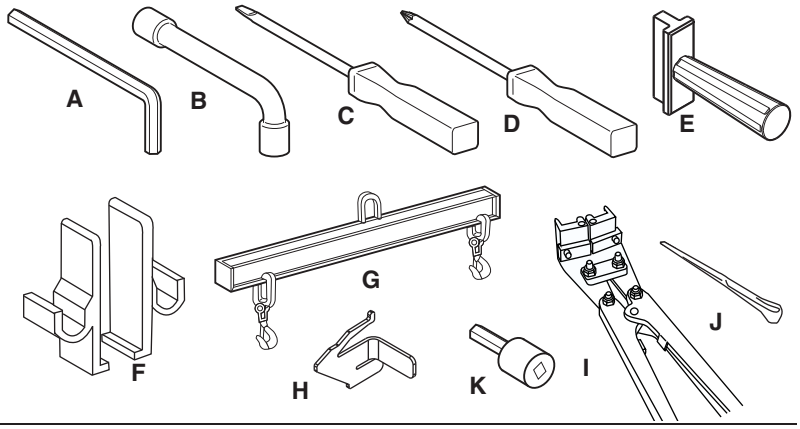
⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH



- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

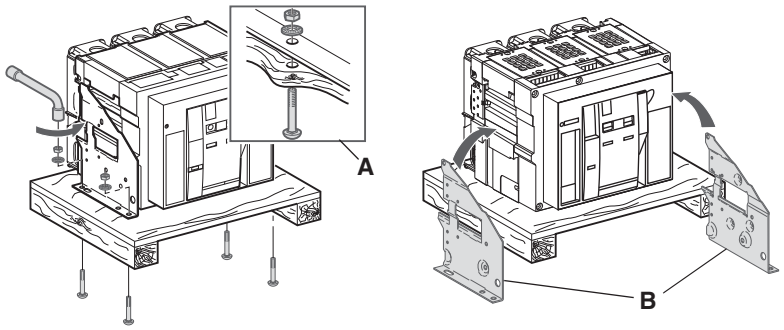
Unpacking and Inspection

NOTE: Repacking instructions can be found in bulletin 0613IB1203, *Masterpact NW Low-Voltage Power/Insulated Case Circuit Breaker–User Guide*, found on the Schneider Electric™ web site (see page 5).



NOTICE
HAZARD OF EQUIPMENT DAMAGE
Do not place circuit breaker on its back. Doing so can damage the clusters.
Failure to follow these instructions can result in equipment damage.

Unpack Circuit Breaker

NOTE: Do not place the circuit breaker on its back. Doing so can damage the clusters.

1. Remove the four bolts, nuts and washers (**Figure 5, A**) securing the circuit breaker to the pallet.
2. On drawout circuit breakers only: remove the shipping brackets (**B**).

Figure 5 – Unpack Circuit Breaker

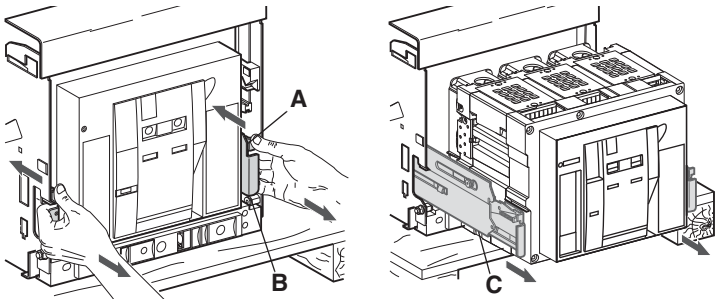
Unpack Circuit Breaker Shipped in Cradle



1. Rack the circuit breaker (**Figure 6, A**) to the disconnected position (**B**) (refer to Drawout Circuit Breaker Disconnection, page 70).

Figure 6 – Disconnect Circuit Breaker

2. Pressing in the latching tabs (**Figure 7, A**), pull out on the extension rail handles (**B**) until the extension rails are fully extended (**C**).

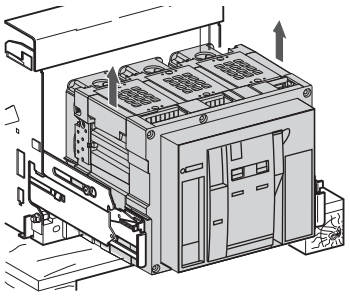


Figure 7 – Pull Out Circuit Breaker

NOTE: Do not place the circuit breaker on its back. Doing so can damage the clusters.

3. Remove circuit breaker. See Cradle Removal, page 37.

Unpack Cradle

1. Remove the four bolts, nuts and washers (Figure 9, A) securing cradle to pallet.
2. Remove cradle from pallet. See Lifting, page 16.

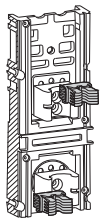
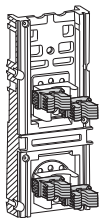
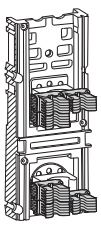
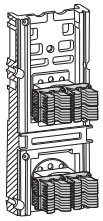
Cluster Inspection, Replacement and Lubrication

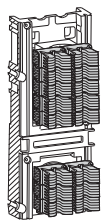
Cluster Inspection

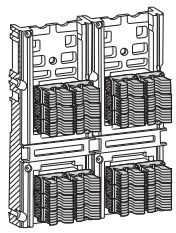












1. Inspect clusters and cluster supports on back of the drawout circuit breaker. Make sure clusters are installed and configured properly as shown in Table 3.
2. Visually inspect clusters for signs of damage such as:
   - — Discolored areas
   - — Visible copper on fingers
   - — Cracked or broken springs
   - — Not aligned with other clusters (indicates spring damage)
3. Visually inspect clusters for wear.

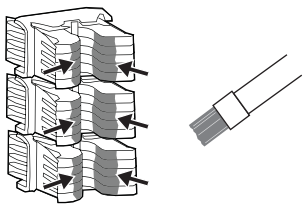
Cluster Lubrication

CAUTION



HAZARD OF EQUIPMENT DAMAGE

Inspect the cluster for lubrication when the circuit breaker is removed from the cradle.

Failure to follow these instructions can result in equipment damage.

Use grease kit (catalog number S48899) to lubricate cluster jaws as shown in Figure 11.

Figure 11 – Cluster Grease Application

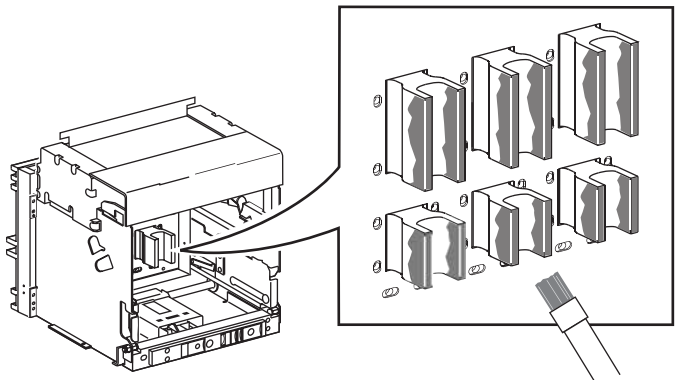
Cradle Stab Lubrication

The cradle stabs must be inspected and lubricated when the cradle is first installed and again during maintenance periods after all power has been disconnected.

⚠ DANGER



HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Confirm that both sides of stab are coated with lubricant. If necessary, use grease kit (catalog number S48899) to lubricate stab.

Section 2— Lifting and Transporting

Both the circuit breaker and cradle have lifting flanges for lifting. To lift circuit breaker, use an overhead lifting device attached to the lifting flanges, following the directions given in this section.

⚠ DANGER

HAZARD OF DEVICE FALLING

- Be sure lifting equipment has lifting capacity for the unit being lifted.
- Follow manufacturer's instructions for use of lifting equipment.
- Wear hard hat, safety shoes and heavy gloves.

Failure to follow these instructions will result in death or serious injury.

Section 3— Drawout Circuit Breaker Installation

Equipment is normally shipped with cradles installed and circuit breakers shipped separately.

For equipment shipped without cradles installed, install cradles as described below.

For equipment shipped with cradles installed, see page 38 for circuit breaker installation.

NOTE: When cradles are shipped separately from equipment:

- Standard-width 800–3000 A and 3200 A circuit breakers can be shipped installed in the cradles;
- Wide-construction 3200 A L1 and 4000–6000 A circuit breakers must be shipped separately.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Cradle Installation

Install Accessories

Install any required cradle accessories which were not factory installed.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

Do not place tools or other materials on top of cradle.

Failure to follow these instructions will result in death or serious injury.

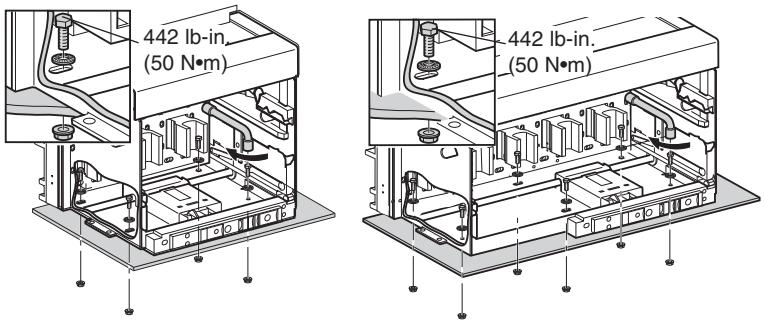
Install Door Escutcheon

If equipment has a door cutout, install the escutcheon shipped with cradle.

1. If not already present, cut opening in the equipment door and drill holes around the opening for the escutcheon. For opening dimensions and hole spacing, refer to bulletin 0613IB1205 on the Schneider Electric™ website (for website information see page 5).
2. Install escutcheon.

Figure 17 – Install Door Escutcheon



Secure Cradle

1. Turn off all power supplying the equipment before working on or inside equipment.

1. If mounting holes are not already present, drill mounting holes in the pan for mounting the cradle. For cradle mounting hole pattern dimensions, refer to bulletin 0613IB1205 on the Schneider Electric website (for website information see page 5).
2. Check flatness of the mounting surface. Surface must be flat to within 0.08 in. (2 mm).
3. Mount the cradle to the pan, using 3/8 in. bolts, washers, and nuts.

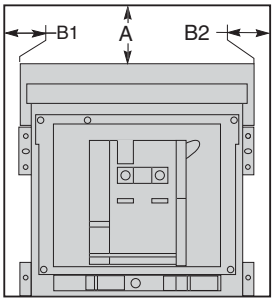
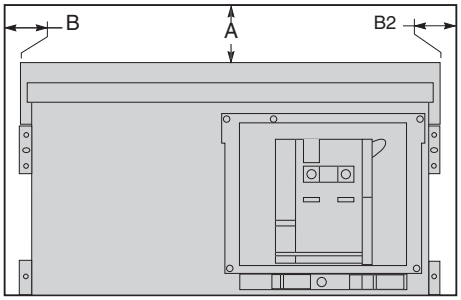
Clearance Requirements



⚠ DANGER



HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

Clearance requirements must be met for proper operation of the equipment.

Failure to follow these instructions will result in death or serious injury.

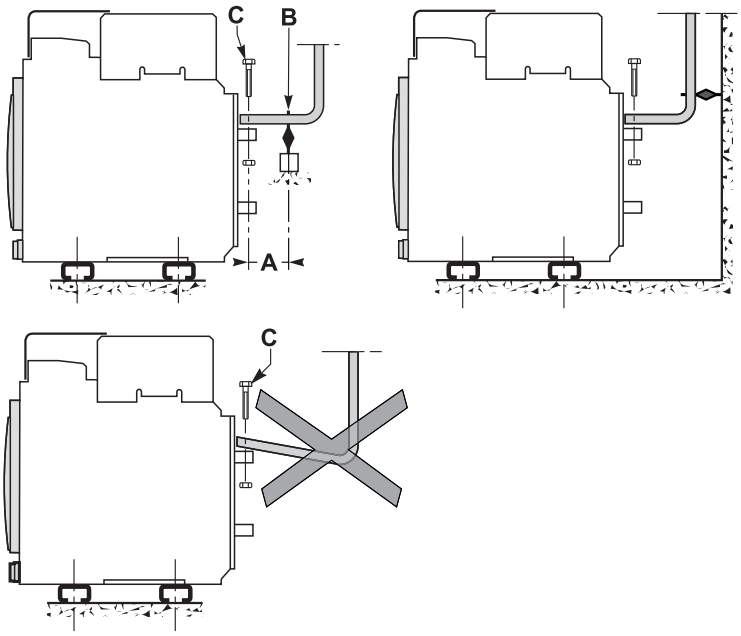
Install Bussing

NOTICE

HAZARD OF EQUIPMENT DAMAGE

The busbar supports must be placed to support the weight of the bussing system and to withstand magnetic forces caused by short-circuit currents. See **Figure 19, A**.



Failure to follow these instructions can result in equipment damage.

NOTE: Installer is responsible for bussing to connectors.

- Bus supports must be braced (**Figure 19, B**) to prevent short circuit forces from deflecting the connectors. The busbar supports (**A**) must be placed to support the weight of the bussing system and to withstand magnetic forces caused by short-circuit currents.
- Busbars should be adjusted to ensure that the connection points are correctly positioned before the bolts (**C**) are inserted. Bussing must be supported by framework of the switchgear, with no weight on connectors.

Bussing requirements by the circuit breaker and connectors are shown in Table 7.

Figure 19 – Busbar Connections

NOTE: The installer is responsible for bussing to the connectors. Bussing must be supported by the framework of the switchgear, with no weight on the connectors. Bus supports must be braced to prevent short circuit forces from deflecting the connectors.

A—Do not remove factory-installed jumpers between Z3, Z4 and Z5 unless ZSI is connected.
B—Do not remove factory-installed jumper between T1 and T2 unless neutral CT is connected. Do not install jumper between T3 and T4.
C—For proper wiring of neutral CT, refer to wiring schematics, pages 32 and 33.
D—24 Vdc power supply for trip unit must be separate and isolated from 24 Vdc power supply for communication modules.

Connections

Masterpact circuit breaker is connected to the ULP devices (FDM121 display, IFM, IFE or IO unit) via the circuit breaker ULP cord.

- Cord is available in three lengths: 0.98 ft. (0.35 m), 4.3 ft. (1.3 m) and 9.8 ft. (3 m).
- Lengths up to 32.9 ft. (10 m) are possible using extensions.

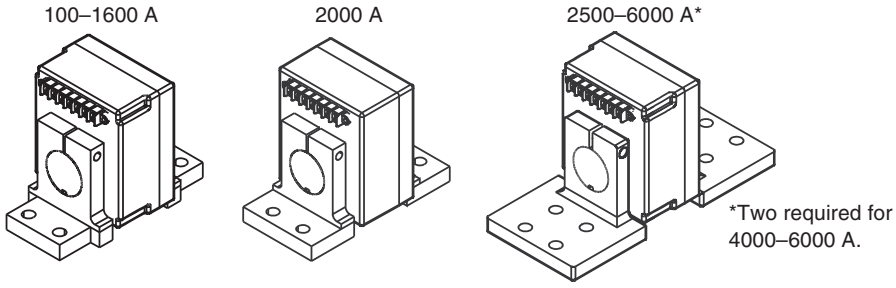
Communicating Shunt Trip (MX) and Shunt Close (XF)

A recommended wiring schematic for the communicating style shunt trip or shunt close coils is shown in Figure 26. Induced voltages in the circuit at terminal C2 and/or A2 can cause the shunt trip or shunt close to not work properly. The best way to prevent the induced voltages is keep the circuit to terminal C2 and A2 as short as possible. If it is impossible to keep the circuit less than ten feet (three meters), use an interposing relay near terminal C2 or A2.

Figure 26 – Communicating Wiring Schematic



Ground-Fault Protection for Equipment

If the circuit breaker does not have an integral ground-fault tripping or alarm, skip this subsection.

A three-phase, four-wire circuit requires an external neutral current transformer (CT).

Figure 27 – Neutral Current Transformers

Connect the neutral CT to the circuit breaker according to wiring diagrams.

1. Connect the primary:
   - — If the load is connected to lower end of the circuit breaker, connect the load neutral to the H1 terminal of the neutral CT.
   - — If the source power is connected to the lower end of the circuit breaker, connect the source neutral to the H1 terminal of the neutral CT.

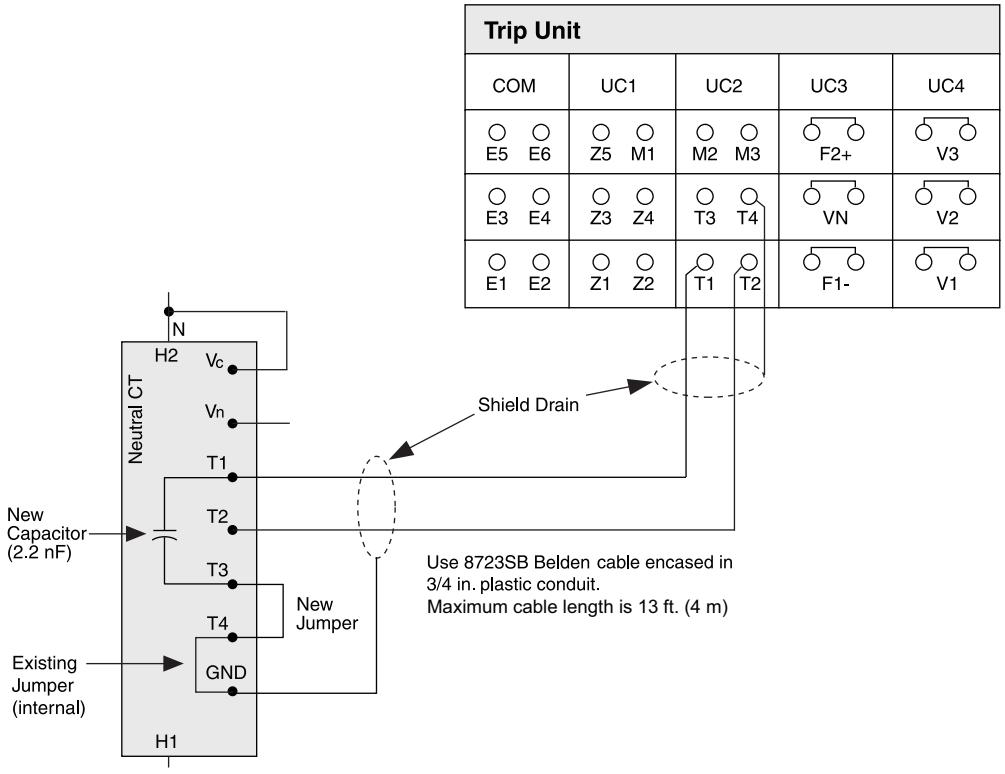
NOTE: The equipment grounding connection must be upstream (line side) of the neutral CT and a neutral connection must exist from the supply transformer to the equipment.

© 2012–2015 Schneider Electric All Rights Reserved

For circuit breakers using Micrologic™ 5.0P, 5.0H, 6.0P, or 6.0H trip units, connect terminal Vn on the neutral current transformer to the Vn terminal of the control wiring terminal. (This is necessary to allow the trip unit to make voltage measurements.) Terminals Vc and Vn are internally connected.

NOTICE

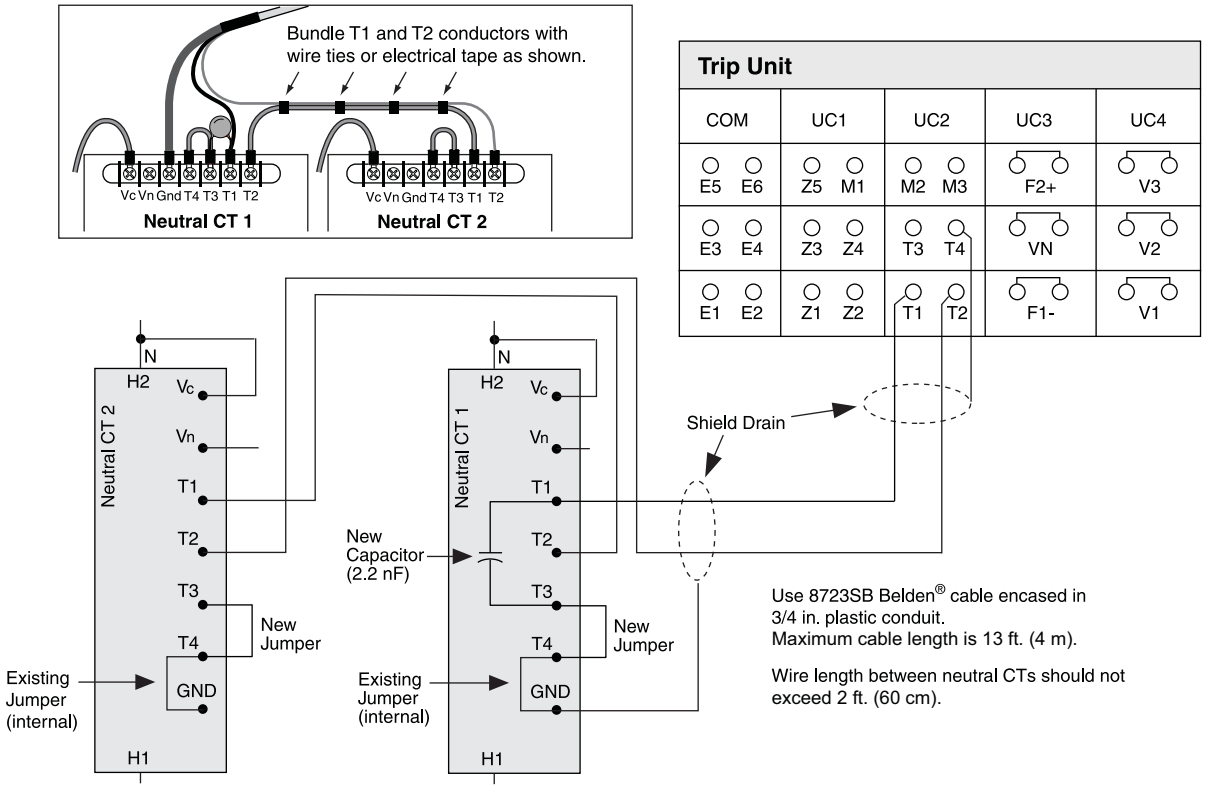
HAZARD OF IMPROPER TRIP SYSTEM OPERATION



F1 and F2 must be isolated from ground. Verify all wiring per the instructions in this bulletin.

Failure to follow these instructions can result in a nuisance trip during closing.

2. Remove the factory-installed jumper connecting T1 and T2.
3. Feed the Belden® cable and plastic conduit from the neutral CT to the cradle terminals.
4. Connect the cable per the appropriate schematic in Figure 28 or 29.
5. Verify all wiring.



NOTE: Modified differential ground-fault circuitry and ground-source return ground-fault circuitry require the use of a modified differential ground-fault module (MDGF) and special current transformers. For wiring of those systems, see the instructions with the MDGF.

Cradle Removal

1. Turn off all power supplying the equipment before working on or inside equipment.
2. Remove the cradle in reverse order of installation.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.

Failure to follow these instructions will result in death or serious injury.

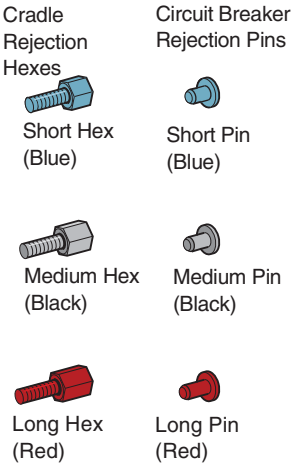
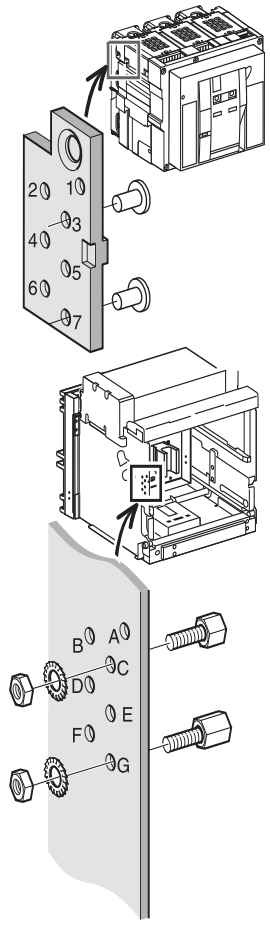
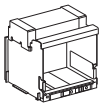
Circuit Breaker Installation

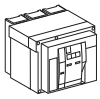


Cradle Rejection Kit



To prevent a Masterpact circuit breaker with an inappropriate ampacity or interrupting rating from being installed in the cradle, install rejection pins on cradle and circuit breaker prior to installing circuit breaker.





1. Determine rejection pin pattern required. (See Table 8 or 9.)

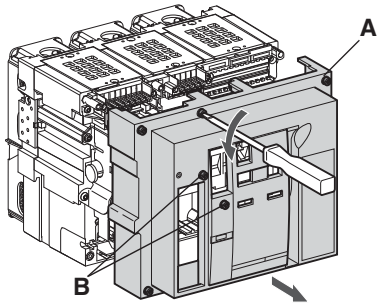
Install Accessories

Install any required circuit breaker accessories which were not factory installed.

If installing electrical accessories, remove accessory cover.

NOTICE
HAZARD OF EQUIPMENT DAMAGE Use caution when removing or replacing the circuit breaker accessory cover. The spring-charging handle (**Figure 44, A**) extends through the circuit breaker accessory cover and can be damaged when removing the accessory cover. **Failure to follow these instructions can result in equipment damage.**

Figure 44 – Spring Charging Handle



Loosen the accessory cover screws and remove the accessory cover (**Figure 45, A**).

NOTE: Screws (**B**) are for Type L, LF, L1, and L1F circuit breakers only.

Install accessory as instructed in the instructions packed with each accessory.

Figure 45 – Remove Accessory Cover

Replace the accessory cover by pulling the handle (**Figure 46, A**) forward and sliding the circuit breaker accessory cover (**B**) down over the handle. Tighten the accessory cover screws.

NOTE: Screws (**C**) are for Type L, LF, L1, and L1F circuit breakers only.

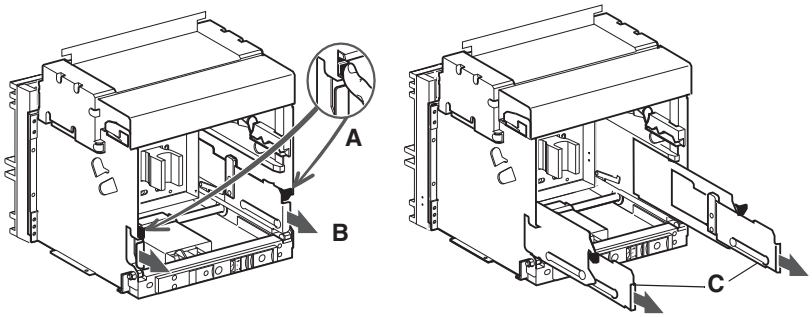
Install Circuit Breaker

NOTICE



HAZARD OF EQUIPMENT DAMAGE

Cradle must be secured when installing or removing circuit breaker.

Failure to follow these instructions can result in equipment damage.

1. Press the latching tabs (**Figure 47, A**), then pull out the extension rail handles (**B**) until the extension rails (**C**) are fully extended.
2. Inspect the circuit breaker clusters for missing or misaligned clusters. See page 11 for information on checking, installing, and lubricating clusters.

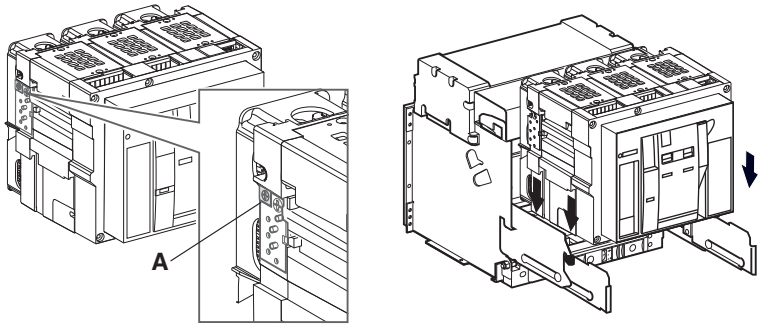
NOTICE

HAZARD OF EQUIPMENT DAMAGE



The shutter actuator must be installed on the circuit breaker for proper operation of cell shutters.

Failure to follow these instructions can result in equipment damage.

3. For cells with shutters, check that the shutter actuator (**Figure 48, A**) is installed on the circuit breaker.
4. Install the circuit breaker on the extension rails. See page 16 for proper lifting equipment.

   NOTE: The cradle must be secured on a pallet if it is not installed in the equipment prior to installing the circuit breaker.

5. Push in the circuit breaker.
6. Connect the circuit breaker. See page 68, Drawout Circuit Breaker Connection for instructions on connecting the circuit breaker.

Test Equipment Ground-Fault Protection

Paragraph 230-95(c) of the National Electrical Code requires that all equipment ground-fault protection systems be tested when first installed. If the circuit breaker has equipment ground-fault protection installed, test it at this time.

Make sure the trip unit is powered. The trip unit is powered if:

- The circuit breaker is closed or bottom-fed and has more than 100 V of load voltage on two phases (P or H trip unit only).
- The full-function or hand-held test kit is connected and on.
- A 24 Vdc external power supply is connected.
- An external voltage tap is installed and a voltage of more than 100 V is present on two phases (P or H trip unit only).

If this is a radial (single-ended) system, press the ground-fault push-to-test button (**Figure 50, A**). The circuit breaker will trip and the trip unit ground-fault indicator light will come on.

Record results in Table 10.

If a complete check of the ground-fault system is necessary, use primary injection testing. If the system has multiple sources and/or requires field connections at the job site, use primary injection testing.

Circuit Breaker Removal

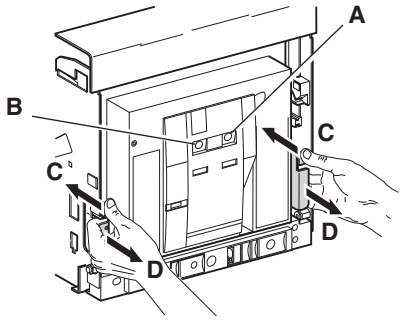
NOTICE

HAZARD OF EQUIPMENT DAMAGE

Cradle must be secured when installing or removing circuit breaker.

Failure to follow these instructions can result in equipment damage.

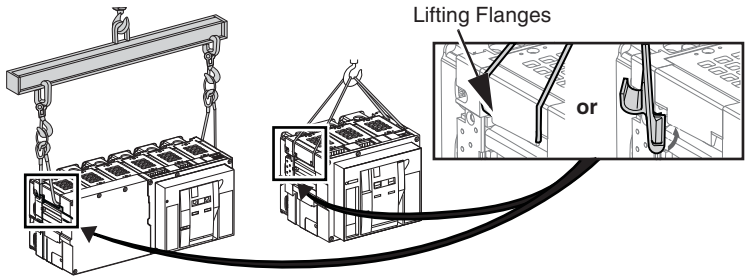
⚠ DANGER



HAZARD OF DEVICE FALLING

- Be sure lifting equipment has lifting capacity for the unit being lifted. Follow manufacturer's instructions for use of lifting equipment.
- Wear hard hat, safety shoes and heavy gloves.

Failure to follow these instructions will result in death or serious injury.



1. Disconnect circuit breaker as detailed on page 70, Drawout Circuit Breaker Disconnection.
2. With the circuit breaker in the disconnected position, press the "push ON" button (**Figure 51, A**) to close the circuit breaker.
3. Press the "push OFF" button (**B**) to open the circuit breaker.
4. Press latching tabs (**C**), then pull out extension rail handles (**D**).

Figure 51 – Circuit Breaker Removal

5. Remove circuit breaker from cradle rails using lifting flanges on sides of circuit breaker, see Section 2—Lifting and Transporting.

Section 4— Fixed-Mounted Circuit Breaker Installation

Circuit Breaker Installation

Turn off all power supplying this equipment before working on or inside equipment.

Install Accessories

Install circuit breaker accessories not purchased as factory installed at this time.

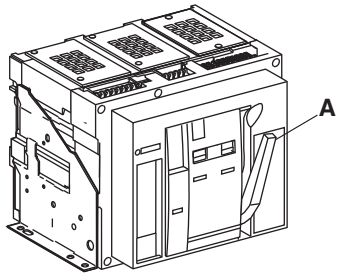
If installing electrical accessories, remove accessory cover.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.



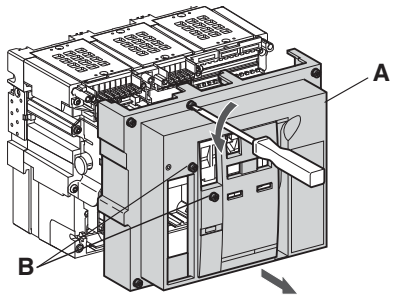
NOTICE

HAZARD OF EQUIPMENT DAMAGE

Use caution when removing or replacing the circuit breaker accessory cover. The spring-charging handle (**Figure 53, A**) extends through the circuit breaker accessory cover and can be damaged when removing the accessory cover.

Failure to follow these instructions can result in equipment damage.

Figure 53 – Spring Charging Handle



© 2012–2015 Schneider Electric All Rights Reserved

1. Loosen the accessory cover screws and remove the accessory cover (**Figure 54, A**).

   NOTE: Screws (**B**) are for Type L and L1 circuit breakers only.
2. Install accessories as instructed in the instructions packed with each accessory.

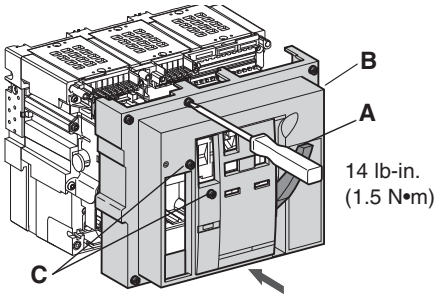


Figure 54 – Remove Accessory Cover

3. Replace the accessory cover by pulling the handle (**Figure 55, A**) forward and sliding the circuit breaker accessory cover (**B**) down over the handle. Tighten the accessory cover screws.

   NOTE: Screws (**C**) are for Type L and L1 circuit breakers only.

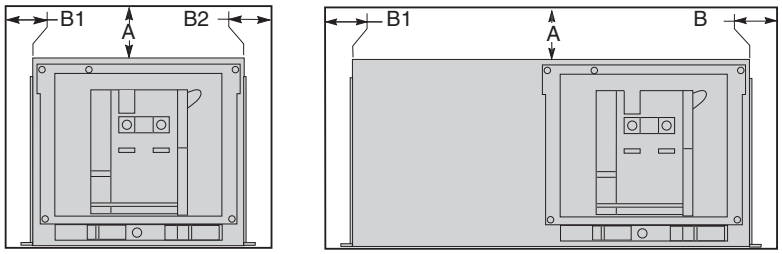
Clearance Requirements



⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

Clearance requirements must be met for proper operation of the equipment.

Failure to follow these instructions will result in death or serious injury.

Install Door Escutcheon

If the equipment has a door cutout, install the escutcheon shipped with circuit breaker.

1. If not already present, cut an opening in the equipment door for the escutcheon. For the opening dimensions, refer to bulletin 0613IB1205 on the Schneider Electric™ website (for website information see page 5).
2. Install the escutcheon.

Figure 56 – Install Door Escutcheon

Install Circuit Breaker

1. If mounting holes are not already present, drill the mounting holes in the pan for mounting the circuit breaker. For circuit breaker mounting hole pattern dimensions, refer to bulletin 0613IB1205 on the Schneider Electric website (for website information see page 5).
2. Check flatness of the mounting surface. Mounting surface must be flat to within 0.08 in. (2 mm).
3. Mount the circuit breaker to pan, using 3/8 in. bolts, washers, and nuts.

NOTE: Vertical mounting brackets are available, if needed.

Install Connectors

Standard connectors are shown in Table 12. Tighten the mounting screws to 142–159 lb-in. (16–18 N•m).

For information on non-standard connectors, contact the field office.

For connector dimensions, refer to bulletin 0613IB1205 on the Schneider Electric website (for website information see page 5).

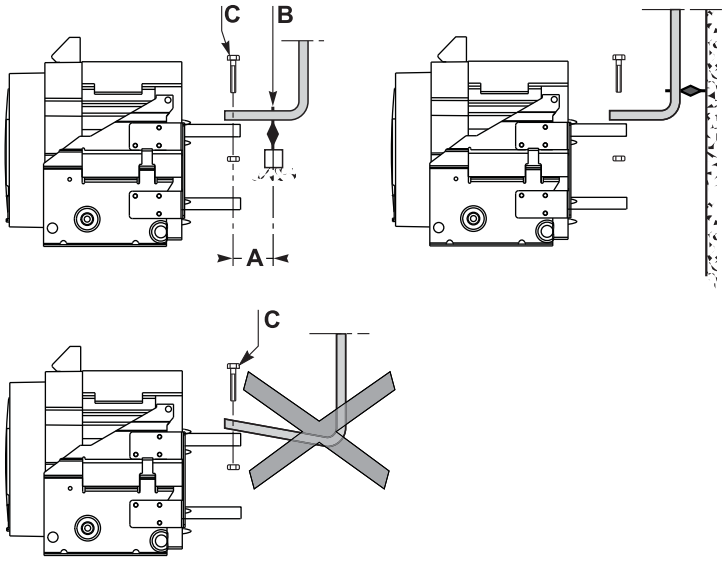
Install Bussing

NOTICE

HAZARD OF EQUIPMENT DAMAGE

The busbar supports must be placed to support the weight of the bussing system and to withstand magnetic forces caused by short-circuit currents. See **Figure 58, A**.



Failure to follow these instructions can result in equipment damage.

NOTE: Installer is responsible for bussing to connectors.

- Bus supports must be braced (**Figure 58, B**) to prevent short circuit forces from deflecting the connectors. The busbar supports (**A**) must be placed to support the weight of the bussing system and to withstand magnetic forces caused by short-circuit currents.
- Busbars should be adjusted to ensure that the connection points are correctly positioned before the bolts (**C**) are inserted. Bussing must be supported by framework of the switchgear, with no weight on connectors.

Bussing requirements by circuit breaker and connector are shown in Table 13.

Figure 58 – Busbar Connections

NOTE: The installer is responsible for bussing to connectors. Bussing must be supported by framework of the switchgear, with no weight on the connectors. Bus supports must be braced to prevent short circuit forces from deflecting the connectors.

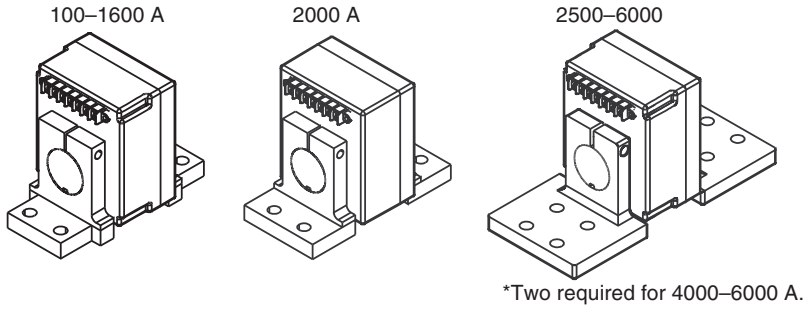
Communicating Shunt Trip (MX) and Shunt Close (XF)

A recommended wiring schematic for the communicating style shunt trip or shunt close coils is shown in Figure 61. Induced voltages in the circuit at terminal C2 and/or A2 can cause the shunt trip or shunt close to not work properly. The best way to prevent the induced voltages is keep the circuit to terminal C2 and A2 as short as possible. If it is impossible to keep the circuit less than ten feet (three meters), use an interposing relay near terminal C2 or A2.

Figure 61 – Communicating Wiring Schematic



Ground-Fault Protection for Equipment

If the circuit breaker does not have integral ground-fault tripping or alarm, skip this subsection.

A three-phase, four-wire circuit requires an external neutral current transformer (CT). Connect the neutral CT to the circuit breaker according to the wiring diagrams in Figures 63 and 64.

Figure 62 – Neutral Current Transformers

*Two required for 4000–6000 A.

1. Connect the primary:
   - — If load is connected to the lower end of the circuit breaker, connect the load neutral to the H1 terminal of neutral CT.
   - — If the source power is connected to the lower end of the circuit breaker, connect the source neutral to the H1 terminal of the neutral CT.

© 2012–2015 Schneider Electric All Rights Reserved

NOTE: The equipment grounding connection must be upstream (line side) of the neutral CT and a neutral connection must exist from the supply transformer to the equipment.

2. For circuit breakers using Micrologic™ 5.0P, 5.0H, 6.0P, or 6.0H trip units, connect terminal Vn on the neutral current transformer to the Vn terminal of the control wiring terminal. (This is necessary to allow the trip unit to make voltage measurements.) Terminals Vc and Vn are internally connected.

CAUTION

HAZARD OF IMPROPER TRIP SYSTEM OPERATION

F1 and F2 must be isolated from ground. Verify all wiring per the instructions in this bulletin.

Failure to follow these instructions can result in a nuisance trip during closing.

3. Remove the factory-installed jumper connecting T1 and T2.
4. Feed Belden cable from the neutral CT to the cradle terminals.
5. Connect the cable per the appropriate schematic in Figure 63 or 64.
6. Verify all wiring.

NOTE: Modified differential ground-fault circuitry and ground-source return ground-fault circuitry require the use of a modified differential ground-fault module (MDGF) and special current transformers. For wiring of those systems, see the instructions with the MDGF.

2. Push a Wago wire insert tool (**Figure 66, A**, Wago part no. 209-129) fully into the connector (to point **B**) and install the control wires (**C**).

NOTE: Remove a push-in connector in reverse order of installation.

Test Equipment Ground-Fault Protection

Paragraph 230-95(c) of the National Electrical Code requires that all equipment ground-fault protection systems be tested when first installed. If the circuit breaker has equipment ground-fault protection installed, test it at this time.

Make sure the trip unit is powered. The trip unit is powered if:

- A full-function or hand-held test kit is connected and on.
- A 24 Vdc external power supply is connected.
- An external voltage tap is installed and voltage of more than 100 V is present on two phases (P or H trip unit only).

If this is a radial (single-ended) system, press the ground-fault push-to-test button (**Figure 67, A**). The circuit breaker will trip and the trip unit ground-fault indicator light will come on.

Record results in Table 15.

If a complete check of the ground-fault system is necessary, use primary injection testing. If the system has multiple sources and/or requires field connections at the job site, use primary injection testing.

Circuit Breaker Removal

1. Turn off all power supplying this equipment before working on or inside equipment.
2. Remove the circuit breaker in reverse order of installation. Use lifting methods as detailed in Section 2—Lifting and Transporting.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Section 5— Trip Unit

Protective functions, measurement functions, and communications are controlled by the Micrologic™ trip unit (**Figure 68, A**) installed in the circuit breaker. The trip unit is field replaceable for easy upgrading of functionality.

For complete information on the trip unit, its functions, and field replacement, see the trip unit user guide available from the Schneider Electric™ website.

For complete information on which trip units are available and their capabilities, see catalog 0613CT1001, *Masterpact NT and NW Universal Power Circuit Breakers* on the Schneider Electric website (for website information see page 5).

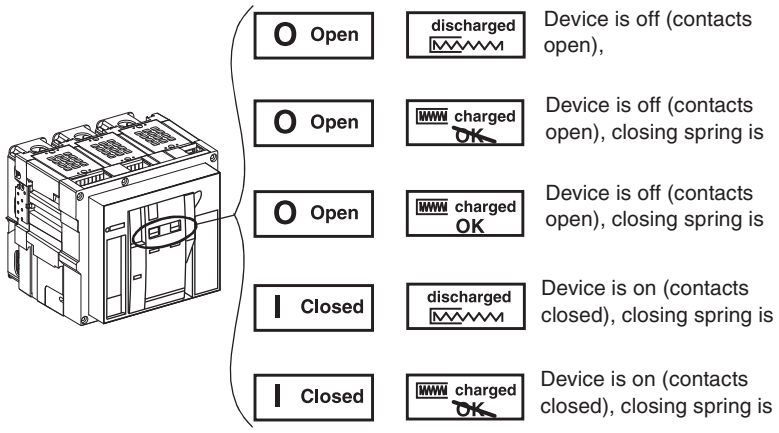

Figure 74 – Rack Circuit Breaker to Disconnected Position

Circuit Breaker Operation

The circuit breaker is closed by means of a two-step stored energy mechanism. Status indicators on the front of the circuit breaker indicate whether the circuit breaker is open or closed, and whether the closing spring is charged or discharged. The opening springs are automatically charged when the circuit breaker closes.

Figure 75 – Status Indicators

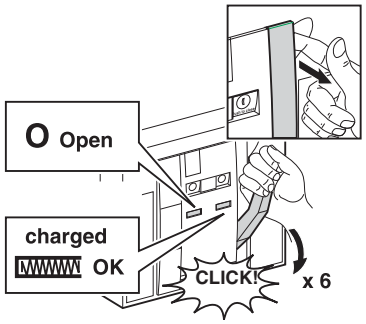
[1] Not OK to turn on will be shown if:
Shunt trip is energized
Circuit breaker is not connected, test, disconnected or withdrawn position
Undervoltage trip is not energized

Anti-Pumping Function

The Masterpact circuit breaker is designed to mechanically provide an anti-pumping function. If either the shunt close or shunt trip coil is continuously powered, or both are powered at the same time, the circuit breaker will open and cannot be closed until the power has been removed. This prevents the circuit breaker from cycling between closing and opening (called pumping).

 © 2012–2015 Schneider Electric All Rights Reserved

When remote operation features are used, make sure there is a minimum of four seconds for the spring charging motor (MCH) to completely charge the circuit breaker closing springs prior to actuating the shunt close (XF) coil. The ready-to-close switch (PF) can be series connected with the shunt close (XF) coil to prevent premature closing.



Charging the Closing Spring

To close the circuit breaker, the closing spring must be charged with sufficient energy for closing.

- Manual Charge: Use the charging handle to charge the closing spring.
- Automatic Charge: If the optional MCH spring-charging motor is installed, the spring is automatically charged after closing.

NOTE: The closing spring on the drawout circuit breaker will automatically discharge when the circuit breaker is moved from the disconnect to the withdrawn position.

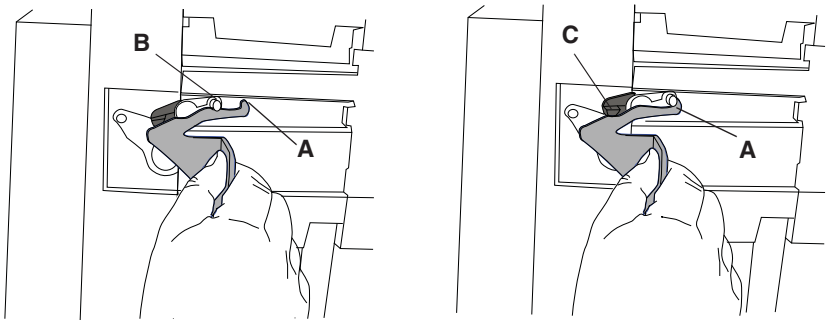


Figure 76 – Manual Spring Charge

NOTE: To close a drawout circuit breaker when it is not installed in the cradle, the cradle interlock must be defeated before the circuit breaker charging spring can be charged. A cradle interlock defeat tool is shipped with every circuit breaker. To install:

1. Slide the interlock defeat tool (**Figure 77, A**) into the groove under the interlock lever (**B**) on the right side of the circuit breaker.
2. Slide the tool toward the front of the circuit breaker and lock it in place under the cradle interlock shaft (**C**).

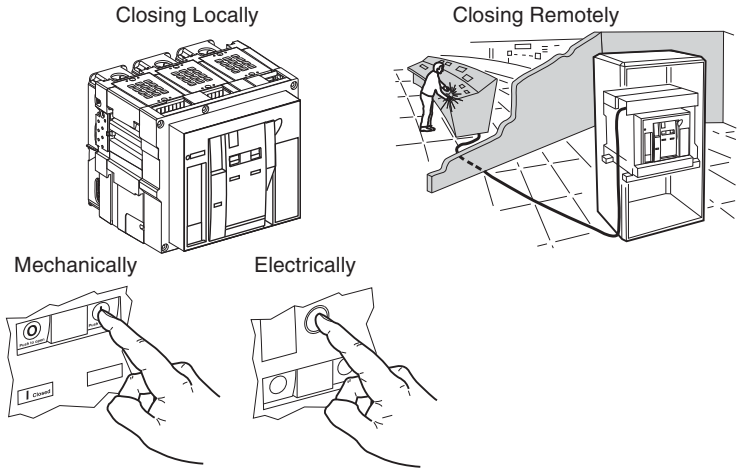
Close Circuit Breaker

To close the circuit breaker, the following conditions must be met:

- The device is open (O).
- The charging spring is charged.
- “OK” is displayed.



NOTE: The circuit breaker cannot be closed while an opening order is being received. If the “not OK” symbol is displayed, an order to open is being received (electrically or manually) and must be ended before the “OK” will be displayed.

If the above conditions are met, close the device:

- Mechanically: press the “Push to close” button on the circuit breaker.
- Electrically: if the optional shunt close (XF) is installed, press the optional electrical-close push button (BPFE) on the circuit breaker or a push button at a remote location.

  For more information, refer to the circuit breaker user guide on the Schneider Electric™ website (for website information see page 5).

Figure 78 – Close Circuit Breaker

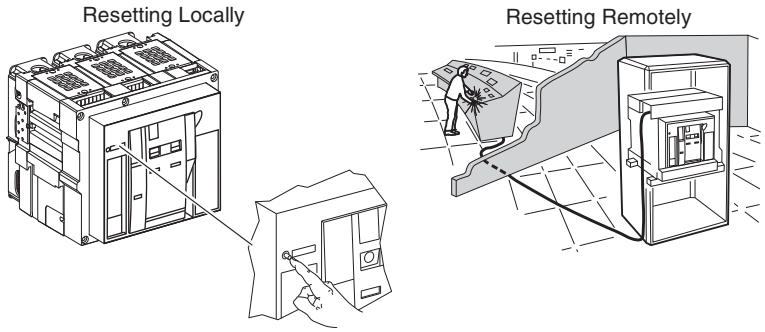
Open Circuit Breaker

- Mechanically: press the “Push to open” button on the circuit breaker.
- Electrically: operate remotely through the optional shunt trips (MX1 and MX2), undervoltage trip device (MN), or time-delay module for undervoltage trip accessory (MNR).

  For more information, refer to the circuit breaker user guide on the Schneider Electric website (for website information see page 5).

Figure 79 – Turn Off Circuit Breaker



Reset Circuit Breaker

After a fault trip, the circuit breaker must be reset.

- Mechanically: press the “Reset” button located above the trip unit.

  Electrically: use the electrical reset option (RES) after an electrical fault. For more information, refer to the circuit breaker user guide on the Schneider Electric website (for website information see page 5).

Neutral Protection

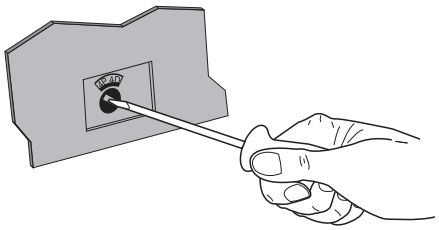
Neutral protection protects the neutral conductors against overheating.

- For a three-pole circuit breaker with a P or H trip unit, neutral protection is possible if a neutral current transformer is used.
  - — Adjust the neutral using the trip unit keypad of the P or H trip unit.
  - — Possible settings are OFF, N/2, N, or 1.6N.
  - — Factory setting is OFF.

Oversize neutral protection (1.6N) requires the use of the appropriate oversize neutral current transformer. See price list for correct neutral current transformer.

NOTICE

HAZARD OF EQUIPMENT DAMAGE



If a four-pole circuit breaker neutral pole switch is set to 4P 3D setting, the current in the neutral must not exceed the rated current of the circuit breaker.

For a three-pole circuit breaker with oversize neutral protection (1.6N), select the appropriate oversize neutral current transformer.

Failure to follow these instructions can result in equipment damage.

- For a four-pole circuit breaker, set the system type using the circuit breaker neutral selector dial (see Figure 81).
  - — With a P or H trip unit, make fine adjustments using the trip unit keypad, with the circuit breaker dial setting providing the upper limit for adjustment.
  - — Factory setting is 4P 4D.

- Neutral protection conductor type has four possible settings:
  - — Off (4P 3D)—Neutral protection is turned off.
  - — N/2 (3P N/2)—Neutral conductor capacity is one-half that of the line conductors.
  - — N (4P 4D)—Neutral conductor capacity is the same as that of the line conductors.
  - — 1.6N—Neutral conductor capacity is 1.6 times that of the line conductors. (Three pole circuit breaker with P or H trip unit only.)

Section 7— Locks, Interlocks, and Accessories

A number of optional locking and interlocking devices and accessories are available for the Masterpact circuit breaker and cradle. The operation of these devices is described in bulletin 0613IB1203: *Masterpact™ NW Low-Voltage Power/Insulated Case Circuit Breaker with ArcBlok Technology—User Guide* available on the Schneider Electric™ website (for website information see page 5).

For a complete listing of the available locks, interlocks, and accessories, see catalog 0613CT1001, *Masterpact NT and NW Universal Power Circuit Breakers* on the Schneider Electric website. For more information, refer to the circuit breaker user guide on the Schneider Electric website (for website information see page 5).

For detailed installation instructions on field-installable locks, interlocks, and accessories refer to the installation instructions shipped with the devices.

Accessories can be installed in an installed circuit breaker or an installed cradle.

Installing Circuit Breaker Accessories

Place the circuit breaker in the disconnect position. See Circuit Breaker Disconnection, page 70, for instructions on disconnecting the circuit breaker.

Install circuit breaker accessories, see “Install Accessories” on page 42.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.

Failure to follow these instructions will result in death or serious injury.

Installing Cradle Accessories

1. Turn off all power supplying this equipment before working on or inside equipment.
2. Remove the circuit breaker from the cradle. See Circuit Breaker Removal, page 46 for instructions on removing the circuit breaker.
3. Install accessory as instructed in the instructions packed with the individual accessory.
4. Replace the circuit breaker in the cradle. See Circuit Breaker Installation, page 38, for instructions on installing the circuit breaker.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Table 18 – Troubleshooting Guide

Problem	Probable Causes	Solutions
Circuit breaker cannot be closed locally or remotely	Circuit breaker padlocked or keylocked in the “OPEN” position.	Disable the locking function.
	Circuit breaker interlocked mechanically in a source changeover system.	• Check the position of the other circuit breaker in the changeover system. • Modify the situation to release the interlock.
	Circuit breaker not completely connected.	Complete racking in (connection) of the circuit breakers.
	The reset button signalling a fault trip has not been reset.	• Clear the fault. • Push the reset button on the front of the circuit breaker.
	Stored energy mechanism is not charged.	• Charge the mechanism manually. • If it is equipped with an MCH spring charging motor, check the supply of power to the motor. If the problem persists, replace the spring charging motor.
	MX opening shunt release (shunt trip) is permanently supplied with power.	There is an opening order. Determine the origin of the order. The order must be cancelled before the circuit breaker can be closed.
	MN undervoltage release (UVR) not supplied with power.	• There is an opening order. Determine the origin of the order. • Check the voltage and the supply circuit (V 0.84 Vn). • If the problem persists, replace the release.
	XF closing release (shunt close) continuously supplied with power, but circuit breaker is not “ready to close” (XF not wired in series with PF contact).	Open the supply of power to the XF closing release, then send the closing order again using the XF, but only if the circuit breaker is “ready to close”.
	Circuit breaker uses a Micrologic P or H trip unit, which has a permanent trip order with minimum voltage and minimum frequency protection in the Trip mode and the trip unit powered.	Disable these protection function son the Micrologic P or H control unit.
Circuit breaker cannot be closed remotely but can be opened locally using the closing pushbutton.	Closing order not executed by the XF closing release (shunt close).	Check the voltage on the supply circuit (0.85–1.1 Vn). If the problem persists, replace the XF release.
Circuit breaker cannot be opened remotely but can be opened locally	Closing order not executed by the MX opening release (shunt trip).	Check the voltage on the supply circuit (0.7–1.1 Vn). If the problem persists, replace the XF release.
	Opening order not executed by the MN undervoltage release (UVR).	Drop in voltage is insufficient or residual voltage (> 0.35 Vn) across the terminals of the undervoltage release. If the problem persists, replace the MN release.
Circuit breaker cannot be opened locally.	Operating mechanism malfunction or damaged contacts.	Contact a Schneider Electric service center.
Circuit breaker can be reset locally but not remotely.	Insufficient supply voltage for the MCH spring charging motor.	• Check the voltage and the supply circuit (0.7–1.1 Vn). • If the problem persists, replace the MCH release.
Unexpected tripping with activation of the reset button signalling a fault trip.	A fault is present: • Overload • Earth fault (ground fault) • Short-circuit detected by the trip unit.	• Determine and clear the causes of the fault. • Check the condition of the circuit breaker before putting it back into service.

© 2012–2015 Schneider Electric All Rights Reserved

Table 18 – Troubleshooting Guide

Problem	Probable Causes	Solutions
Unexpected tripping without activation of the reset button signalling a fault	MN undervoltage release (UVR) supply voltage too low.	Check the voltage on the supply circuit (V>0.58 Vn).
	Load-shedding order sent to the MX opening release (shunt trip).	• Check the overall load on the distribution system. • If necessary, modify the settings of the devices in the installation.
	Unnecessary opening order from the MX opening release (shunt trip).	Determine the origin of the order.
Instantaneous opening after each attempt to close the circuit breaker with activation of the reset button signalling a fault trip.	Thermal memory.	• See the trip unit user manual. • Press the reset button.
	Transient overcurrent when closing.	• Modify the distribution system or the trip unit settings. • Check the condition of the circuit breaker before putting it back into service. • Press the reset button.
	Closing on a short-circuit.	• Clear the fault. • Check the condition of the circuit breaker before putting it back into service. • Press the reset button.
Nuisance tripping of the circuit breaker with activation of the reset button signalling a fault trip.	Reset button is not pushed in completely.	Push the reset button in completely.
Cannot insert crank in connected, test, or disconnected position.	A padlock or keylock is present on the cradle or a door interlock is present.	Disable the locking function.
Cannot turn the crank.	The reset button has not been pressed.	Press the reset button while turning racking handle (crank).
Circuit breaker cannot be removed from the cradle.	Circuit breaker is not in the disconnected position.	Turn the racking handle (crank) until the circuit breaker is in the disconnected position and the reset button is out.
	The rails are not completely out.	Pull the rails all of the way out.
	Racking handle (crank) has not been removed from the racking mechanism.	Remove and store the racking handle.
Circuit breaker cannot be racked in (placed in connected position).	Cradle/ circuit breaker mismatch protection (cell keying) is preventing racking.	Check that the cradle corresponds with the circuit breaker.
	The disconnecting-contact clusters are incorrectly positioned.	Reposition the clusters.
	Cradle is locked in the disconnected position.	Disable the cradle locking function.
	The reset button has not been pressed, preventing rotation of the crank.	Press the reset button while turning racking handle (crank).
	The circuit breaker has not been sufficiently inserted into the cradle.	Insert the circuit breaker completely so that it is engaged in the racking mechanism.
Circuit breaker cannot be locked in disconnected position.	The circuit breaker is not in the right position.	Check the circuit breaker position by making sure that the rest button is out.
	Racking handle (crank) has not been removed from the racking mechanism.	Remove and store the racking handle.
Circuit breaker cannot be locked in connected or test position.	Check that locking in any position is enabled.	Contact a Schneider Electric service center.
	The circuit breaker is not in the right position.	Check the circuit breaker position by making sure the reset button is out.
	Racking handle (crank) has not been removed from the racking mechanism.	Remove and store the racking handle.
The crank cannot be inserted to connect or disconnect the circuit breaker.	The rails are not completely in.	Push the rails all the way in.
The right-hand rail of the cradle or the circuit breaker cannot be drawn out.	Racking handle (crank) has not been removed from the racking mechanism.	Remove and store the racking handle.

Hazard Categories and Special Symbols

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to potential personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates a hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a hazardous situation which, if not avoided, **can result in** death or serious injury.

NOTICE

NOTICE is used to address practices not related to physical injury. The safety alert symbol is not used with this signal word.

NOTE: Provides additional information to clarify or simplify a procedure.

Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

FCC Notice

This equipment has been tested and found to comply with the limits for a Class A digital device, pursuant to part 15 of the FCC Rules. These limits are designed to provide reasonable protection against harmful interference when the equipment is operated in a commercial environment. This equipment generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with the instruction manual, may cause harmful interference to radio communications. Operation of this equipment in a residential area is likely to cause harmful interference in which case the user will be required to correct the interference at his own expense. This Class A digital apparatus complies with Canadian ICES-003.

Section 1— General Information

Introduction

The Masterpact NW low-voltage power circuit breaker[1] and insulated case circuit breaker are designed to mount in a drawout cradle, using rear-mounted, plug-on pressure connections to provide electrical connection to the cradle. A fixed-mounted circuit breaker is also available.

Operating Conditions

Masterpact circuit breakers can be used:

- At ambient temperatures between -13°F (-25°C) and 158°F (70°C) Mechanical closing of the circuit breaker (by pushbutton) is possible down to -31°F (-35°C)
- Altitude ≤ 13,000 ft. (3900 m)

Operating at other that 104°F (40°C) and at altitudes greater than 6600 ft. (2000 m) may require re-rating, overbussing, heating, or cooling. See Tables 2 and 3 for re-rating values for both UL 489 and UL 1066 (ANSI C37.50) Listed circuit breakers. For 122°F (50°C) overbussing with no derating, contact the field office.

Masterpact circuit breakers have been tested for operation in industrial atmospheres. It is recommended that the equipment be cooled or heated to the proper operating temperature (max. 104°F [40°C]) and kept free of excessive vibration and dust.

Before Working on Circuit Breaker

1. Turn circuit breaker off:

   Press “Push to close” button (**Figure 4, A**) to discharge spring, as indicated by window (**B**).

   Press “Push to open” button (**C**) to open contacts, as indicated by window (**D**).

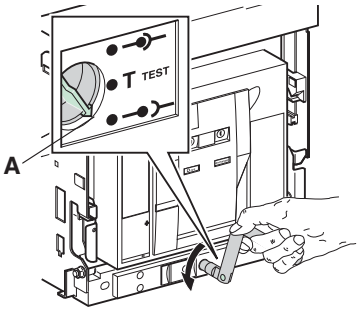
⚠ DANGER



HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.

Failure to follow these instructions will result in death or serious injury.

— For drawout circuit breaker: rack circuit breaker to disconnected position (**Figure 5, A**). See Drawout Circuit Breaker Disconnection, page 24.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

For fixed-mounted circuit breaker: turn off all power supplying equipment before working on or inside equipment.

Section 2— Lifting and Transporting

Both the circuit breaker and cradle have lifting flanges for lifting. To lift circuit breaker, use an overhead lifting device attached to the lifting flanges, following the directions given in this section.

⚠ DANGER

HAZARD OF DEVICE FALLING

- Be sure lifting equipment has lifting capacity for the unit being lifted.
- Follow manufacturer's instructions for use of lifting equipment.
- Wear hard hat, safety shoes and heavy gloves.

Failure to follow these instructions will result in death or serious injury.

Section 3— Trip Unit

Protective functions, measurement functions and communications are controlled by the Micrologic™ trip unit (**Figure 13, A**) installed in the circuit breaker. The trip unit is field replaceable for easy upgrading of functionality.

For complete information on the trip unit, its functions and field replacement, see the trip unit user guide. For complete information on trip unit availability and capabilities, refer to catalog 0613CT1001, Masterpact NT and NW Universal Power Circuit Breakers. Section 4— Operation

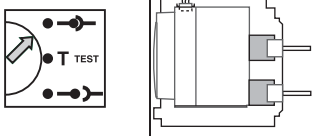
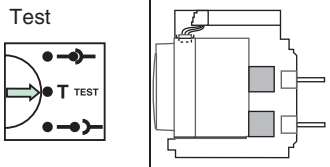
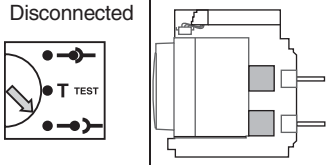
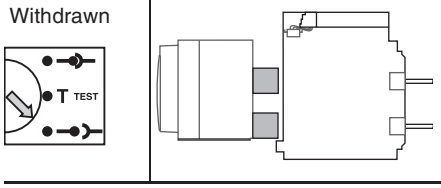
Drawout Circuit Breaker Status

⚠ DANGER









HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.

Failure to follow these instructions will result in death or serious injury.

Connection or disconnection of the drawout circuit breaker requires insertion of the racking handle (while pressing “Push to open” button). If interlocks, padlocks or an open door lock are in place, the racking handle cannot be inserted.

Circuit Breaker Removal

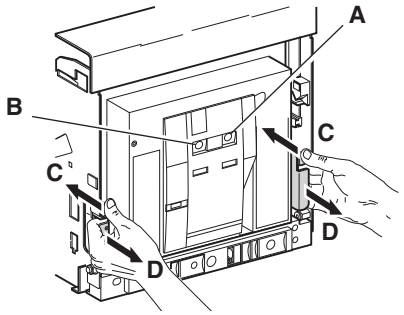
NOTICE

HAZARD OF EQUIPMENT DAMAGE

Cradle must be secured when installing or removing circuit breaker.

Failure to follow these instructions can result in equipment damage.

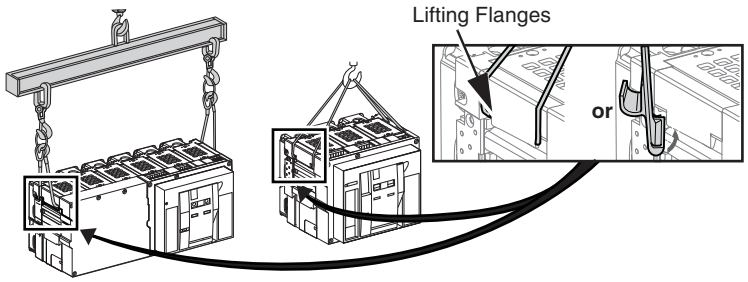
⚠ DANGER



HAZARD OF DEVICE FALLING

- Be sure lifting equipment has lifting capacity for the unit being lifted. Follow manufacturer's instructions for use of lifting equipment.
- Wear hard hat, safety shoes and heavy gloves.

Failure to follow these instructions will result in death or serious injury.



1. Disconnect circuit breaker as detailed on page 24, Drawout Circuit Breaker Disconnection.
2. With the circuit breaker in the disconnected position, press the "push ON" button (**Figure 24, A**) to close the circuit breaker.
3. Press the "push OFF" button (B) to open the circuit breaker.
4. Press latching tabs (**C**), then pull out extension rail handles (**D**).

Figure 24 – Circuit Breaker Removal

5. Remove circuit breaker from cradle rails using lifting flanges on sides of circuit breaker, see Section 2—Lifting and Transporting.

Figure 25 – Overhead Lifting

Circuit Breaker Operation

The circuit breaker is closed by means of a two-step stored energy mechanism. Status indicators on the front of the circuit breaker indicate whether the circuit breaker is open or closed, and whether the closing spring is charged or discharged. Opening springs are automatically charged when the circuit breaker closes.

Figure 26 – Status Indicators

[1]It is not OK to turn device on if:

- Shunt trip is energized.
- Circuit breaker is not in connected, test, disconnected or withdrawn position.
- Undervoltage trip is not energized.
- Mechanical interlock is locking mechanism in the open position.

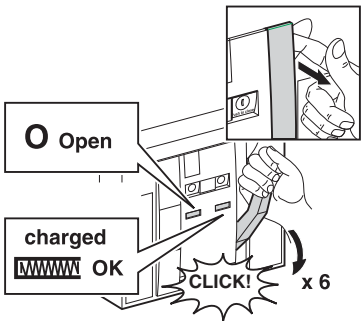
Anti-Pumping Function

The Masterpact circuit breaker is designed to mechanically provide an anti-pumping function. If either the shunt close or shunt trip coil is continuously powered, or both are powered at the same time, the circuit breaker will open and cannot be closed until the power has been removed. This prevents the circuit breaker from cycling between closing and opening (called pumping).

If the circuit breaker is equipped with a communicating-style shunt trip or shunt close (see page 48), the operation of the coil is impulse only. The plungers in the coils do not maintain an interlock on the closing mechanism. An opening signal and a closing signal cannot be sent simultaneously.

When remote operation features are used, make sure there is a minimum of four seconds for the spring charging motor (MCH) to completely charge the circuit breaker closing springs prior to actuating the shunt close (XF) coil. The ready-to-close switch (PF) (see page 47) can be series connected with the shunt close (XF) coil to prevent premature closing.

 © 2012–2015 Schneider Electric All Rights Reserved



Charging the Closing Spring

To close the circuit breaker, the closing spring must be charged with sufficient energy for closing.

- Manual Charge: Use charging handle to charge closing spring.
- Automatic Charge: If the optional MCH spring-charging motor is installed, the spring is automatically charged after closing.

NOTE: The closing spring on the drawout circuit breaker will automatically discharge when the circuit breaker is moved from disconnect to withdrawn position.

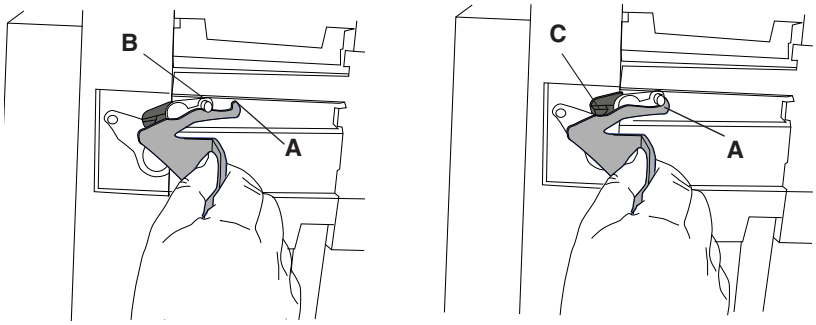


Figure 27 – Manual Spring Charge

NOTE: To close a drawout circuit breaker when it is not installed in the cradle, the cradle interlock must be defeated before the circuit breaker charging spring can be charged. A cradle interlock defeat tool is shipped with every circuit breaker. To install:

1. Slide the interlock defeat tool (**Figure 28, A**) into the groove under the interlock lever (**B**) on the right side of the circuit breaker.
2. Slide the tool toward the front of the circuit breaker and lock it in place under the cradle interlock shaft (**C**).

Figure 28 – Defeating Cradle Interlock

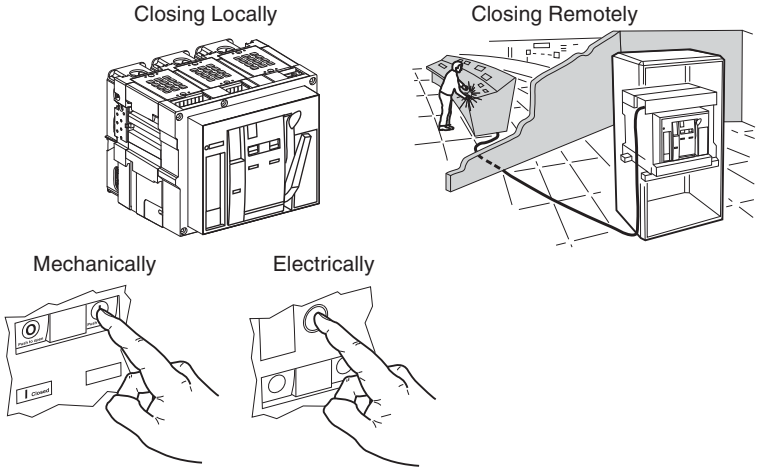
Close Circuit Breaker

To close the circuit breaker, the following conditions must be met:

- The device is open (O).
- The charging spring is charged.
- “OK” is displayed.



NOTE: The circuit breaker cannot be closed while an opening order is being received. If the “not OK” symbol is displayed, an order to open is being received (electrically or manually) and must be ended before the “OK” will be displayed.

If the above conditions are met, close the device by:

- Mechanically: press the “Push to close” button on the circuit breaker.
- Electrically: if the optional shunt close (XF) is installed, press the optional electrical-close push button (BPFE) on the circuit breaker or a push button at a remote location.

See pages 48 and 49 for more information about these options.

Figure 29 – Close Circuit Breaker

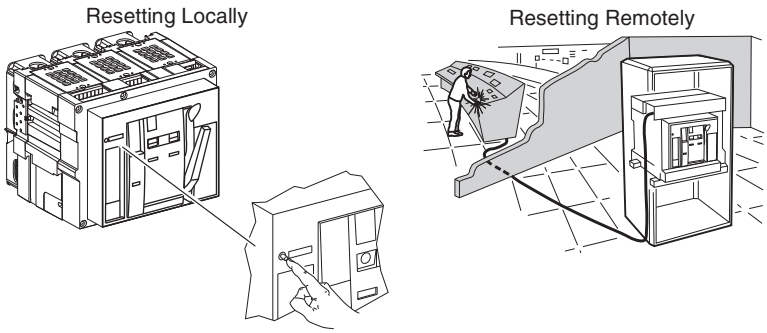
 © 2012–2015 Schneider Electric All Rights Reserved

Open Circuit Breaker

- Mechanically: press “Push to open” button on the circuit breaker.
- Electrically: remotely operate using the optional shunt trips (MX1 and MX2), undervoltage trip device (MN), or time-delay module for undervoltage trip accessory (MNR).

See pages 49 and 49 for more information about these options.

Figure 30 – Turn Off Circuit Breaker



Reset Circuit Breaker

After a fault trip, the circuit breaker must be reset.

- Mechanically: press the “Reset” button located above the trip unit.
- Electrically: use the electrical reset option (RES) after an electrical fault. See page 47 for more information about this option.

Figure 31 – Reset Circuit Breaker

Neutral Protection

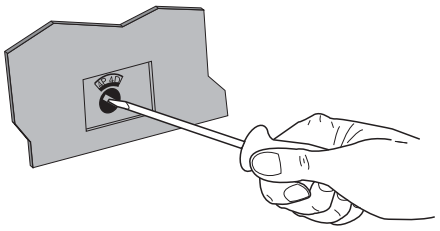
Neutral protection protects the neutral conductors against overheating.

- For a three-pole circuit breaker with a P or H trip unit, neutral protection is possible if a neutral current transformer is used.
  - — Adjust the neutral using the trip unit keypad of the P or H trip unit.
  - — Possible settings are OFF, N/2, N, or 1.6N.
  - — Factory setting is OFF.

Oversize neutral protection (1.6N) requires the use of the appropriate oversize neutral current transformer. See price list for correct neutral current transformer.

CAUTION

HAZARD OF EQUIPMENT DAMAGE



If a four-pole circuit breaker neutral pole switch is set to 4P3D setting, the current in the neutral must not exceed the rated current of the circuit breaker.

For a three-pole circuit breaker with oversize neutral protection (1.6N), select the appropriate oversize neutral current transformer.

Failure to follow these instructions can result in equipment damage.

- For a four-pole circuit breaker, set the system type using the circuit breaker neutral selector dial (see **Figure 32**).
  - — With a P or H trip unit, make fine adjustments using the trip unit keypad, with the circuit breaker dial setting providing the upper limit for adjustment.
  - — The factory setting is 4P 4D.

- The neutral protection conductor type has four possible settings:
  - — Off (4P 3D)—Neutral protection is turned off.
  - — N/2 (3P N/2)—Neutral conductor capacity is one-half that of the line conductors.
  - — N (4P 4D)—Neutral conductor capacity is the same as that of the line conductors.
  - — 1.6N—Neutral conductor capacity is 1.6 times that of the line conductors. (3P circuit breaker with P or H trip unit only.)

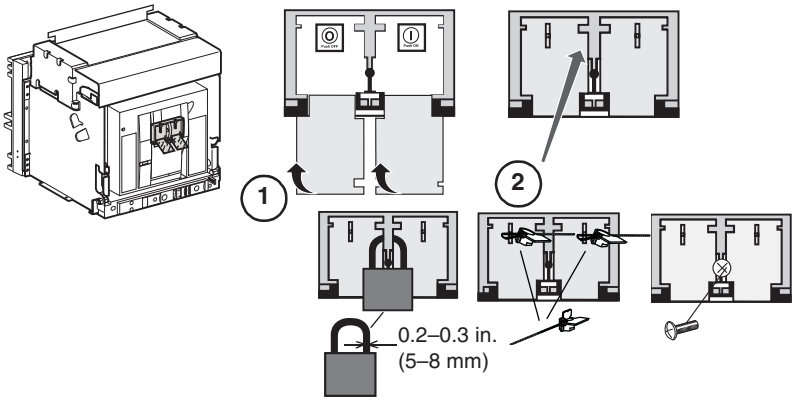
Section 5— Locks and Interlocks

A number of optional locking and interlocking devices are available for the Masterpact circuit breaker and cradle. The operation of most of these devices is described in this section. For a complete listing of available locks and interlocks, see catalog 0613CT1001, *Masterpact NT and NW Universal Power Circuit Breakers* on the Schneider Electric™ website.

For detailed installation instructions on field-installable locks and interlocks, refer to the installation instructions shipped with the devices.

Push Button Lock



The push button lock prevents the circuit breaker from being opened or closed using the push buttons.

- Optional.
- Can be secured with a padlock, sealing lead or two screws.

To Lock:

1. Install the push button lock over the “Push to open” and “Push to close” buttons.
2. Close the plastic covers of the lock.
3. Lock the plastic cover in place using a padlock, wire seal, or screws.

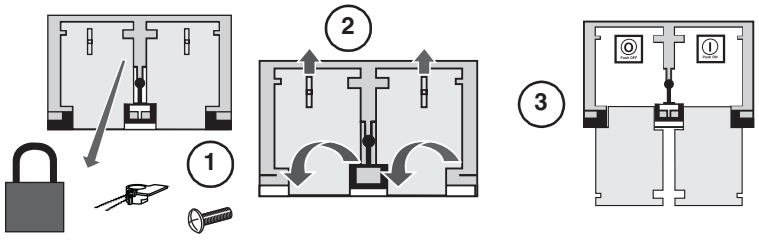


Figure 33 – To Lock Push Buttons

To Unlock:

1. Remove the padlock, wire seal, or screws.
2. Open the plastic covers of lock.
3. The buttons can be pushed.

Figure 34 – To Unlock Push Buttons

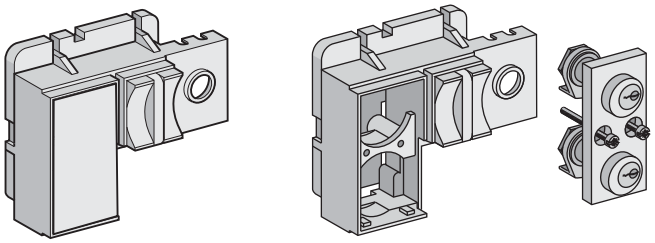
Open Position Padlock and Open Position Padlock with Key Lock



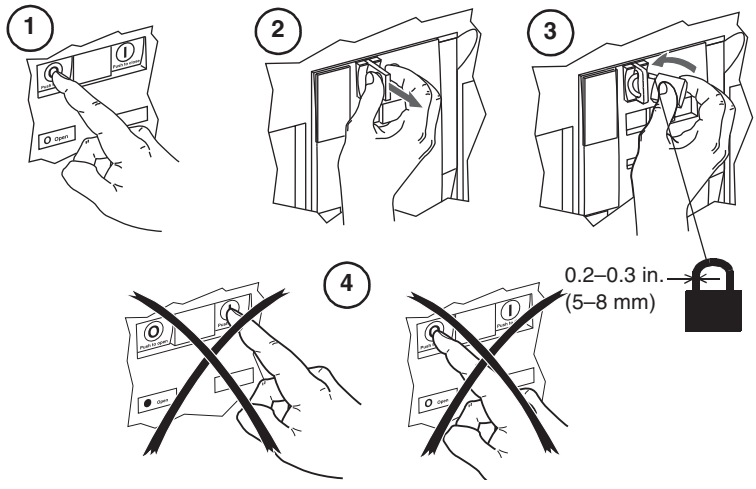
The padlocks prevent the circuit breaker from being closed, either with the push buttons or remotely.

- Optional.
- Secured with one to three padlocks.

The open position padlock and key lock is:

- Optional.
- Available with the Kirk® key lock
- Can be secured with:
  - — One padlock;
  - — One or two key locks;
  - — Or both.

Figure 35 – Open Position Padlock and Open Position Padlock and Key Lock



Locking with a Padlock

To Lock (**Figure 36**):

1. Open the circuit breaker.
2. Pull out the tab.
3. Attach the padlock.
4. Verify the controls are disabled.

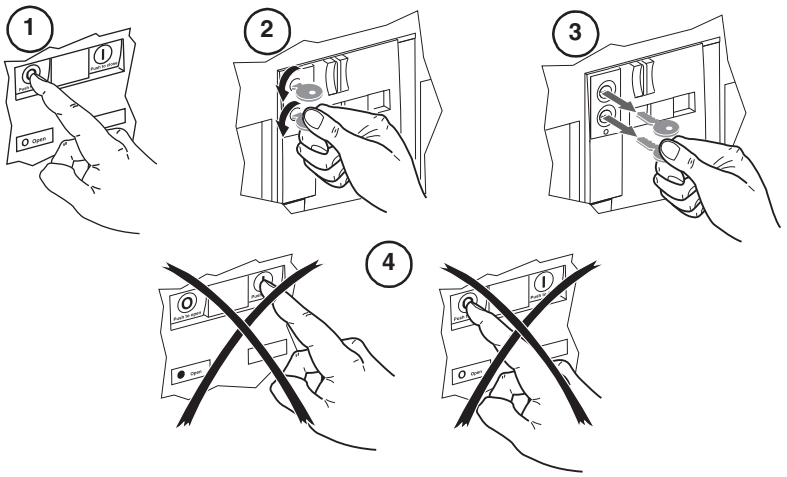
To Unlock (**Figure 37**), remove the padlock.

Figure 37 – Remove the Padlock



Locking with a Key Lock

To Lock (**Figure 38**):

1. Open the circuit breaker.
2. Turn the key(s).
3. Remove the key(s).
4. Verify the controls are disabled.

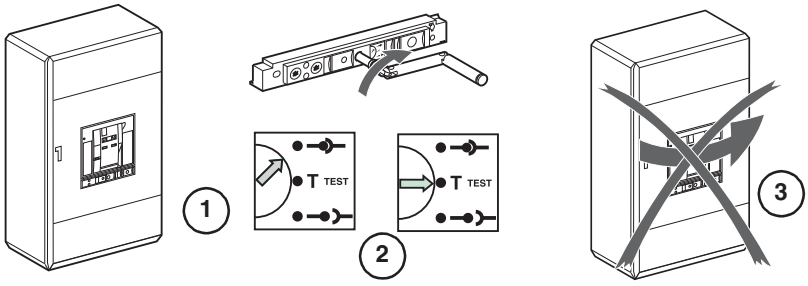
Equipment Door Interlock

If the door lock accessory is installed, the equipment door can only be opened when the circuit breaker is in the disconnected position.

- For drawout circuit breaker only.
- Optional.
- Normally mounts on the right side of the cradle.
- Can be ordered for mounting on the left of the cradle.
- Allows the door to be closed with the circuit breaker in any position.

Table 8 – Door Interlock



Circuit Breaker Position	Interlock Hook	Door
Connected	Lowered	Locked
Test	Lowered	Locked
Disconnected	Raised	Unlocked

To Lock (**Figure 40**):

1. Close the enclosure door.
2. Move the circuit breaker to the test or connected position.
3. Verify the door is locked.

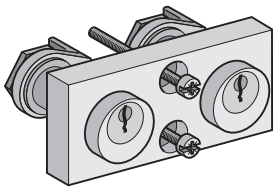
To Unlock (**Figure 41**):

1. Move the circuit breaker to the disconnected position.
2. Verify the door is unlocked.

Figure 41 – Unlocking the Door Interlock



Cradle Locks

The cradle locks prevent the drawout circuit breaker from being racked in or out (by preventing insertion of racking handle) and from being moved from the disconnected position to the fully withdrawn position (by locking the drawout rails).

- Secured with one to three padlocks (standard) and/or with one or two key locks (optional).
- Keylocks are available with the Kirk key lock.
- Allows the cradle to be locked in any position (connected, test, and disconnected).
- Mounted on the cradle.

Locking Cradle with a Padlock (Standard)

To Lock (**Figure 43**):

1. Make sure the cradle indicator is in the disconnected, test, or connected position.
2. Pull out the tab.
3. Attach the padlock(s).
4. Verify racking handle cannot be inserted.

NOTE: If circuit breaker is padlocked in disconnected position, the circuit breaker cannot be pulled out from the disconnected position to the fully withdrawn position.

Locking Cradle with a Key Lock

To Lock (**Figure 45**):

1. Make sure the cradle indicator is in the disconnected, test, or connected position.
2. Turn the key(s).
3. Remove the key(s).
4. Verify the racking handle cannot be inserted.

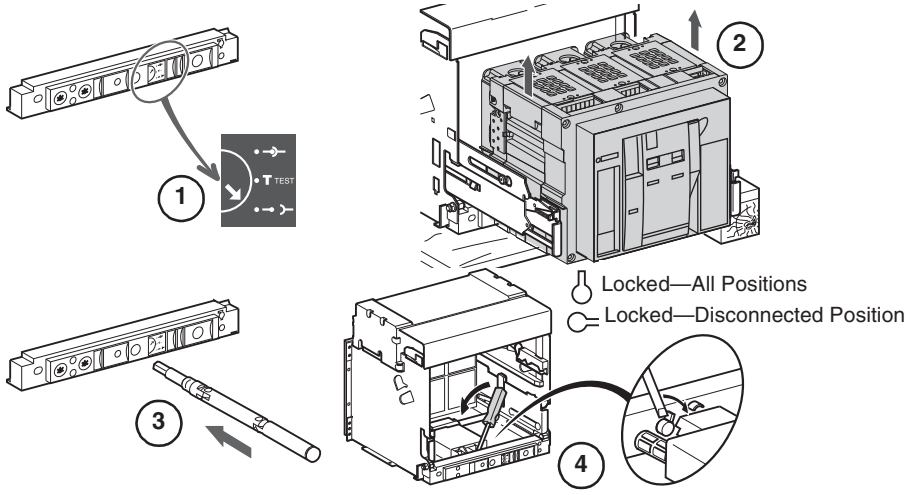
Cradle in Any Position Locks



Padlocks and/or key locks used to lock the cradle in the disconnected position can be converted to lock the device in any position (connected, test, or disconnected).

To convert the lock (**Figure 47**):

1. Make sure cradle indicator is in the disconnected position.
2. Remove the circuit breaker from the cradle. (See circuit breaker removal instructions).
3. Insert the racking handle.
4. Rotate the latch to the left. The cradle can now be locked in any position.

NOTE: To return cradle to locking only in the disconnected position, rotate latch to the right.

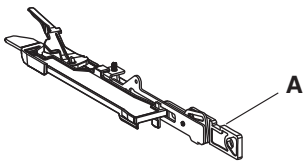
Open Door Racking Interlock

The open door racking interlock prevents the racking handle from being inserted if the equipment door is open.

- Optional.
- Mounts on the right side of the cradle.

To deactivate, pull out the interlock (**Figure 48, A**).

Figure 48 – Interlocking Cradle Position



Shutter Lock

The shutter lock (**Figure 49, A**) is used to prevent connection of the circuit breaker by locking the shutter in the closed position.

- Optional.
- Allows the shutter to be padlocked.

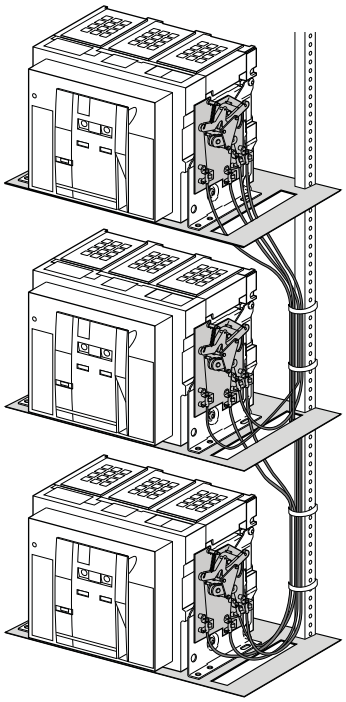
Cable Door Interlock

The cable door interlock prevent the panel door from being opened if the circuit breaker is closed.



- Optional.
- Must be installed after the circuit breaker is installed in the enclosure.

Source Changeover Interlock

The source changeover interlock kit provides interlocking between three circuit breakers.

- Kit S48608 provides interlocking between two “main” circuit breakers connected to the same power source and a third circuit breaker connected to a generator power source.
  - — Four interlocking positions are possible.
  - — The generator circuit breaker is “locked open” when either or both of the main circuit breakers are closed.
- Kit S48609 provides interlocking between two “main” circuit breakers connected to the same power source and one “tie” or external source circuit breaker.
  - — The tie circuit breaker can be in first, second or third position.
  - — Two of the three circuit breakers can be in the closed position at any given time.
- Kit S48610 provides interlocking between three “main” circuit breakers connected to a single power source.
  - — Only one of the three circuit breakers can be in the closed position at any give time.
  - — The other two circuit breakers will be held in the “locked open” position.

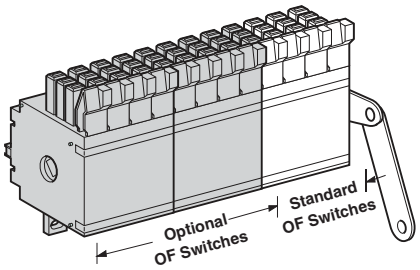
Section 6— Accessories



This section describes commonly used accessories. For a complete listing of available accessories, see catalog 0613CT1001, *Masterpact NT and NW Universal Power Circuit Breakers* on the Schneider Electric™ website.

Auxiliary Switches (OF)

Auxiliary switches (OF) change state when the minimum isolating distance between the main contacts is reached.

- Standard, four switches per circuit breaker, rated 10 A.
- Optional additional OF switches available, rated 6 A:
  - — Two blocks of four additional OF switches are available with push-in terminal blocks.
  - — One block of four additional OF switches are available with ring terminal blocks.
- Indicates the position of the main contacts on the circuit breaker.
- Form C contacts, NO/NC with common neutral.

Figure 52 – Switches (OF)

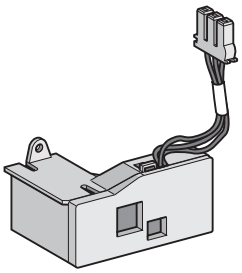
ENGLISH

Connected/Closed Switches (EF)

Connected/closed switches (EF) combine “connected device” and “closed device” information, indicating “the circuit is closed.”

- Optional.
- Maximum of eight switches per circuit breaker with push-in terminal blocks.
- Each switch becomes associated with an OF switch when installed in its connector location.
- Form C contacts, NO/NC with common neutral.
- Not available with ring terminal connector.

Figure 53 – Switches (EF)

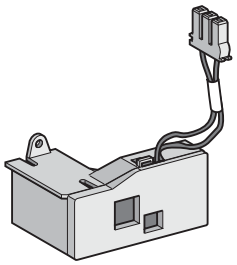


Overcurrent Trip Switch (SDE)

The overcurrent trip switch (SDE) provides remote indication that the circuit breaker has opened because of an electrical fault.

- Standard
- Not available on non-automatic switches
- One form C contacts, NO/NC with common neutral

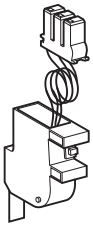
Additional Overcurrent Trip Switch (SDE2)



The additional overcurrent trip switch (SDE2) provides remote indication that the circuit breaker has opned because of an electrical fault.

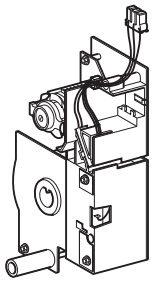
- Optional.
- Not available on non-automatic switches
- Not compatible with RES option
- One form C contact, NO/NC with common neutral

© 2012–2015 Schneider Electric All Rights Reserved



Electric Reset (RES)

The electric reset (RES) resets the circuit breaker remotely after an electrical fault.



- Optional
- Not compatible with SDE2 option

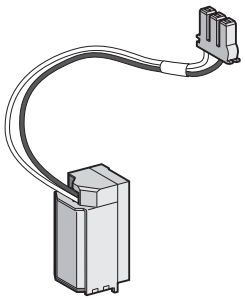
Ready-to-Close Switch (PF)

- The ready-to-close switch (PF) indicates that the following conditions are met and the circuit breaker can be closed:
  - — The circuit breaker is open.
  - — The closing springs are charged.
  - — The circuit breaker in not locked/interlocked in open position.
  - — There is no standing closing order.
  - — There is no standing opening order.
- Optional.
- One form C contacts used for push-in connector, NO/NC with common neutral.
- NO contact used for ring terminal connector.

Spring-Charging Motor (MCH)

The spring-charging motor (MCH) charges the closing springs automatically after the circuit breaker closes.

- Optional
- Charging time: 4 seconds maximum
- Operating rate: 3 cycles/minute, maximum
- Minimal voltage: 0.85–1.1 of rated voltage
- Maximum power consumption: 180 VA



Spring-Charged Contact (CH)

The spring-charged contact (CH) indicates that the circuit breaker is charged.

- Standard with the spring-charging motor
- Form C contacts, NO/NC with common neutral

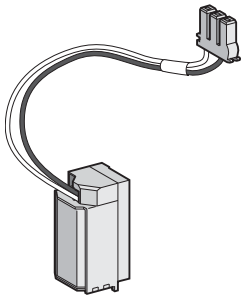
Shunt Trip (MX1 / MX1-COM / MX2)
Shunt Close (XF / XF-COM)

Shunt trip: opens the circuit breaker when energized.

Shunt close: closes the circuit breaker when energized, if the device is ready to close.

NOTE: For a circuit breaker having a circuit breaker communications module (BCM) installed, order MX1-COM and/or XF-COM. These will have three wires instead of the two shown in the illustration.

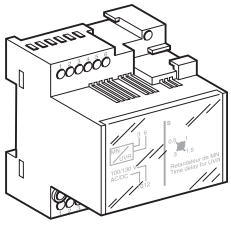


- Optional.
- One or two shunt trips per circuit breaker.
- One shunt close per circuit breaker.
- Shunt trip and shunt close are the same coil, their action is determined by the location of the coil.
- Circuit breaker response time
  - — MX1, MX1-COM and MX2 opening time:
    50 ms ± 10 ms
  - — XF and XF-COM closing time:
    70 ms ± 10 ms for NW ≤ 4000 A
    80 ms ± 10 ms for NW > 4000 A

  NOTE: Shunt trip (MX1) and shunt close (XF) circuits must be energized for a minimum of 200 ms.
- Operating thresholds:
  - — MX1, MX1-COM, and MX2:
    0.7 to 1.1 x rated voltage
  - — XF and XF-COM:
    0.85 to 1.1 x rated voltage
- Continuous power supply possible (continuous duty).
  For MX1-COM/XF-COM use the comm command for continuous duty. The bypass circuit through terminal C2/A2 is only for momentary duty (0.5 sec. max).
- Maximum power consumption: 4.5 VA maintained, 200 VA inrush.
- MX1-COM can be operated remotely by the circuit breaker communication module (BCM).

XF-COM can be operated remotely by either the electrical close button (BPFE) or the circuit breaker communication module (BCM).

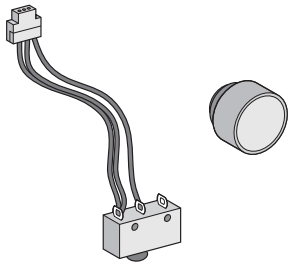
 © 2012–2015 Schneider Electric All Rights Reserved



Undervoltage Trip (MN)

The undervoltage trip (MN) opens the circuit breaker when its supply voltage drops below the threshold voltage.

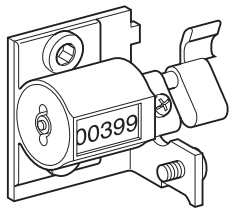
- Optional
- Not compatible with the MX2 shunt trip
- Response time: 90 ms (+5 ms/-5 ms)
- Operating thresholds:
  - — Opening: 0.35 to 0.7 x rated voltage
  - — Closing: 0.85 x rated voltage
- Continuous power supply required to keep circuit breaker closed
- Maximum power consumption: 20 VA



Time-Delay Module for Undervoltage Trip (MNR)

The time-delay module for the undervoltage trip (MNR) can be used to set an adjustable time delay before the undervoltage trip opens the circuit breaker in order to prevent nuisance tripping from a momentary voltage drop. The time-delay mechanism is connected in series with the undervoltage trip (MN) and is installed outside of the circuit breaker.

- Optional
- Available in fixed or adjustable delay versions:
  - — Delay time: 0.5 s, 1 s, 1.5 s, 3 s
  - — Fixed time: 0.25 s



Electrical Closing Push Button (BPFE)

The electrical closing push button (BPFE) closes the circuit breaker electrically using the shunt close (XF).

- Optional
- Located on accessory cover of circuit breaker
- Requires installation of shunt close (XF-COM)
- Cannot be used in combination with a communication module

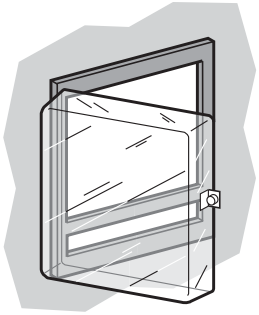
Operations Counter (CDM)

The operations counter (CDM) registers the total number of operating cycles for the circuit breaker.

- Optional
- Can be installed on circuit breaker with or without spring charging motor

 © 2012–2015 Schneider Electric All Rights Reserved

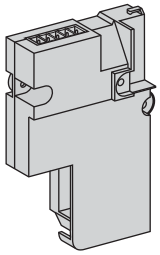
Door Escutcheon (CDP)



The door escutcheon (CDP) provides an IP40, IK07 (equivalent to NEMA 1) seal for the door.

- Standard

Figure 54 – Door Escutcheon (CDP)



Transparent Cover (CCP)

Mounted on the door escutcheon (CDP), the transparent cover (CCP) provides a IP55, IK10 (equivalent to NEMA 3R/12) seal.

- Optional
- Drawout circuit breaker only

Circuit Breaker Communication Module (BCM)

The circuit breaker communications module (BCM) provides communication between circuit breaker trip unit and the communication network.

- Optional on 3.0A, 5.0A, and 6.0A trip units.
- Standard on 5.0P, 6.0P, 5.0H, and 6.0H trip units.
- Not compatible with the 3.0 or 5.0 trip units.
- Dedicated switches can be used to read status of circuit breaker.
- Actuators (MX/XF) can be used to control the circuit breaker.

 © 2012–2015 Schneider Electric All Rights Reserved

I/O (Input/Output) Module

The I/O (input/output) application module for low-voltage circuit breakers links the communication network with the circuit breaker communication module. It connects the Masterpact circuit breaker to a ULP (Universal Logic Plug) system with built-in functions and applications.

- Delivered with the drawout circuit breakers ordered with the COM option for cradle management.
- Must be installed on a DIN rail near the device.
- Must be connected to the ULP system and to the position contacts (CD, CT, CE) that transmit the position of the device in the cradle.
- Compliant with the ULP system specifications.
- Two I/O application modules can be connected in the same ULP network.

The I/O application module resources are:

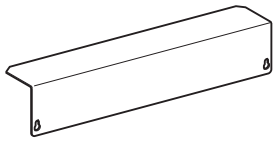
- Six digital inputs that are self powered for either NO and NC dry contact or pulse counter.
- Three digital outputs that are a bistable relay (5 A maximum).
- One analog input for PT100 temperature sensor.

Ethernet Interface Module (IFE)

The IFE interface and IFE interface + gateway enable Masterpact NW circuit breakers to be connected to an Ethernet network.

- Provides an Ethernet access to one or several LV circuit breakers.
- Functions:
  - — Interface: connects one circuit breaker to the IFE interface using its ULP port.
  - — Gateway: connects several circuit breakers on a Modbus network using the IFE interface + gateway master Modbus port.
- Dual 10/100 Mbps Ethernet port for simple daisy chain connection.
- Device profile web service for discovery of the IFE interface, IFE interface + gateway on the LAN.
- ULP compliant for placing the IFE interface in the switchboard.
- Ethernet interface for Masterpact circuit breakers.
- Gateway for Modbus-SL connected devices (IFE interface + gateway only).
- Embedded set-up web pages.
- Embedded monitoring web pages.
- Embedded control web pages.
- Built-in e-mail alarm notification.

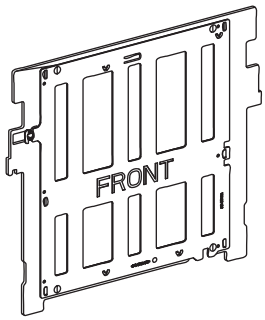
© 2012–2015 Schneider Electric All Rights Reserved



Modbus Interface Module (IFM)

An IFM Modbus communication interface is required for connection of a Masterpact circuit breaker to a Modbus network.

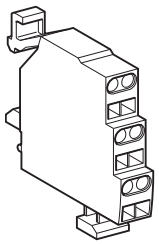
- Requires the circuit breaker be provided with a ULP port. The port is available on the BCM embedded module.
- The IFM is defined as an IMU (Intelligent Modular Unit) in the ULP connection system documentation.
- Connects the circuit breaker as a slave to the Modbus master. Its electrical values, alarm status, open/close signals can be monitored or controlled by a Programmable Logic Controller or any other system.



Terminal Cover (CB)

The terminal cover (CB) prevents access to the accessory terminal blocks.

- Drawout circuit breaker only
- Optional
- Mounts on the cradle



Shutters

The shutters automatically block access to the primary connectors when the circuit breaker is in the test or disconnected position.

- Drawout circuit breaker only
- Optional
- For information on locking the shutters, see page 42

Cradle Position Switch (CE, CD, and CT)

The cradle position switch (CE, CD, or CT) indicates the circuit breaker position in the cradle.

- Drawout circuit breaker only
- Optional
- One to three position switches for each type:
  - — CE: Connected
  - — CD: Disconnected
  - — CT: Test
- Normally-open and normally-closed contacts
- Available as push-in connector switch (shown) or ring tongue terminal connector switch

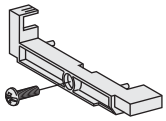
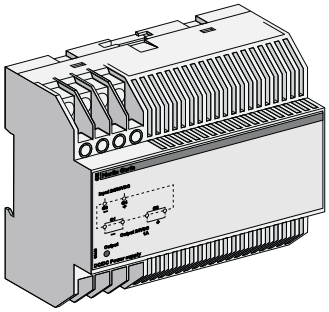
Metering Current Transformers



The metering current transformer is used to scale line currents down to usable values for measuring or control purposes.

- Optional (for drawout circuit breaker only)
- Mounts inside the cradle
- Accurate with the 0.3% accuracy class
- Five ampere output at full load
- A standard wiring harness is provided when metering current transformers are factory mounted

Figure 55 – Metering Current Transformers



Sensor Plugs

The sensor plug is used to set the current sensor rating (In) of the circuit breaker.

- Standard
- Field replaceable

External Power Supply Module

The external power supply module is used with the Micrologic™ A, P, and H trip units to provid.e external power to the trip unit.

- Optional
- Makes it possible to:
  - — Display currents less than 20% of sensor (In)
  - — Maintain display of last trip unit status even after opening of circuit breaker
  - — Store in memory the value of the interrupted current and time-stamp event (P and H trip units only)
- Provides power to the circuit breaker communication module and the cradle communication module
- Field replaceable
- Output:
  - — voltage: 24 Vdc
  - — current: 1 A
  - — ripple < 5%.
- Input Voltage:
  - — Vac: 110–130, 200–240, 380–415
  - — Vdc: 24–30, 48–60, 100–125
  - — 10 VA/10 W consumption

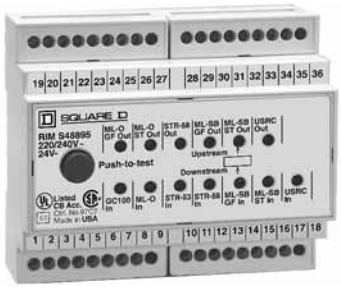
Programmable Contact Modules (M2C and M6C)



Programmable contact modules (M2C and M6C) are used to indicate the type of fault and the instantaneous and delayed threshold overruns.

- Optional
- For Micrologic P and H trip units only
- Programmable via the trip unit or through the communications network
- Requires 24 Vdc power supply
- Contact ratings:
  - — 5 A/240 Vac
  - — 1.8 A/24 Vdc
  - — 1.5 A/48 Vdc
  - — 0.4 A/125 Vdc

Figure 56 – Programmable Contact Modules (M2C and M6C)

Restraint Interface Module (RIM)

The restraint interface module (RIM) allows zone-selective interlocking communications between circuit breakers with Micrologic trip units and other select devices.

- Optional
- For Micrologic A, P, and H trip units only
- Requires external power supply:
  - — 120 Vac or 24 Vdc
  - — 220/240 Vac or 24 Vdc

© 2012–2015 Schneider Electric All Rights Reserved

Ground-Fault Interface Module (MDGF/SGR)

The ground-fault interface module provides interface between trip unit types A, P, or H (with MDGF or SGR) and MDGF sensor(s).

- Optional
- Field installable
- For use on circuit breakers with 400 A or higher sensor.

Figure 57 – Ground-Fault Interface Module (MDGF/SGR) and Sensor

Hand-Held Test Kit

The hand-held test kit is used to verify trip unit operation and the tripping and pole-opening sequence.

- Optional
- Can also be used to:
  - — Inhibit thermal imaging for primary injection testing
  - — Inhibit ground fault for primary injection testing
  - — Self-restrain zone-selective interlocking (ZSI)
  - — Supply control power to the trip unit for settings via the keypad when the circuit breaker is open (Micrologic A, P, and H trip units only)

 © 2012–2015 Schneider Electric All Rights Reserved

Full-Function Test Kit

The full-function test kit is used to verify LSIG functionality.

- Optional
- Can be used to check trip unit operation, for example:
  - — Display of settings
  - — Operating tests on the electronic component
  - — Automatic and manual tests on protection functions (trip curve verification)
  - — Tests on the zone-selective interlocking (ZSI) functions
  - — Inhibit thermal imaging for primary injection testing
  - — Inhibit ground fault for primary injection testing
  - — Self-restrain zone-selective interlocking (ZSI)
- Can also be used to:
  - — Check mechanical operation of the circuit breaker
  - — Check the electrical continuity of the connection between the MITOP (tripping coils) and the trip unit

Print the trip unit and circuit breaker test report when used in conjunction with a PC (FFTK Report Generator software, Catalog No. FFTKRPT-V1-0, is required

Section 7— Installing Accessories

Accessories can be installed in an installed circuit breaker or an installed cradle.

Installing Circuit Breaker Accessories

Drawout Circuit Breaker

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.

Failure to follow these instructions will result in death or serious injury.

Place circuit breaker in disconnect position. See Drawout Circuit Breaker Disconnection, page 24, for instructions on disconnecting the circuit breaker.

Fixed-Mounted Circuit Breaker

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Turn off all power supplying this equipment before working on or inside equipment.

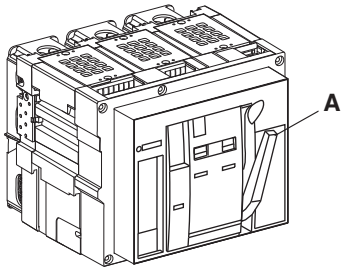
Install Circuit Breaker Accessories



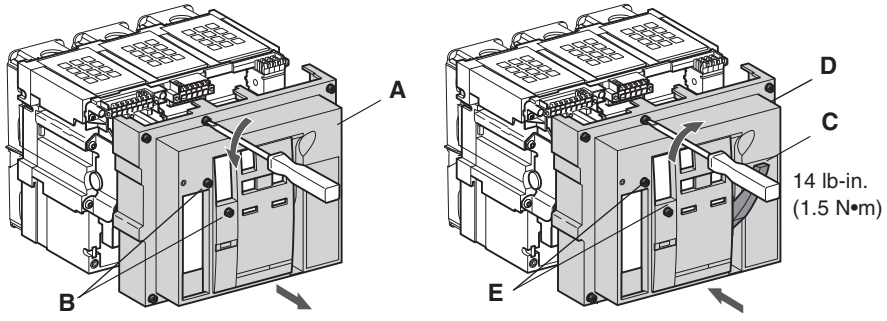
NOTICE

HAZARD OF EQUIPMENT DAMAGE

Use caution when removing or replacing the circuit breaker accessory cover. The spring-charging handle (**Figure 58, A**) extends through the circuit breaker accessory cover and can be damaged when removing the accessory cover.

Failure to follow these instructions can result in equipment damage.

Figure 58 – Spring Charging Handle



If installing electrical accessories, remove the accessory cover.

1. Loosen the accessory cover screws and remove the accessory cover (**Figure 59, A**).

   NOTE: Screws (**B**) are for Type L, LF, L1 and L1F circuit breakers only.
2. Install accessories as instructed in the instructions packed with the individual accessory.
3. Replace the accessory cover by pulling the spring-charging handle (C) forward and sliding the circuit breaker accessory cover (D) down over the handle. Tighten the accessory cover screws.

   NOTE: Screws (E) are for Type L, LF, L1 and L1F circuit breakers only.

Drawout Circuit Breaker

The drawout circuit breaker can now be placed back in connected position. See Drawout Circuit Breaker Connection, page 22 for instructions on connecting the circuit breaker.

Fixed-Mounted Circuit Breaker

The fixed-mounted circuit breaker can now be placed back in service.

Installing Cradle Accessories

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

1. Turn off all power supplying this equipment before working on or inside equipment.
2. If circuit breaker is installed in cradle, remove it following the instructions in “Circuit Breaker Removal” on page 27.
3. Install each accessory as instructed in the instructions packed with the individual accessory.
4. Replace the circuit breaker in the cradle, see “Circuit Breaker Installation” on page 25.

The drawout circuit breaker can now be placed back in connected position. See Drawout Circuit Breaker Connection, page 22 for instructions on connecting the circuit breaker.

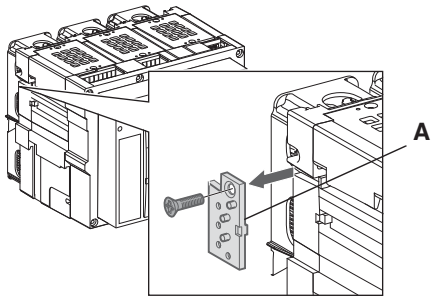
Section 9— Repacking

Materials Required



- Pallet
- Packing Carton
- Shipping Brackets, insert nuts and bolts
- Four Carriage Bolts, 3/8 x 12, 2 in. (50 mm) long minimum
- Four Washers, 3/8 in.
- Four Nuts, 3/8 x 12

Repacking

Repacking Circuit Breaker

1. If drawout circuit breaker is installed in the cradle, remove it following the instructions in “Circuit Breaker Removal” on page 27.
   If fixed-mounted circuit breaker is installed in equipment, remove it following the instructions in the bulletin shipped with the circuit breaker.
2. Remove the rejection pin plate (**Figure 60, A**) from side of the circuit breaker, if installed.

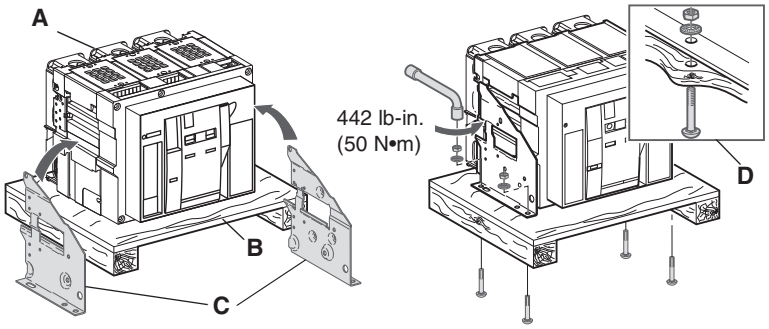
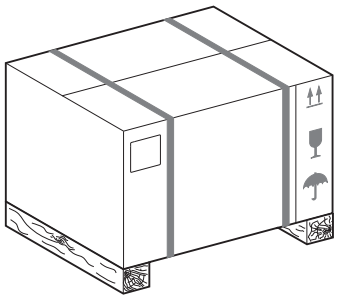
NOTICE



HAZARD OF EQUIPMENT DAMAGE

Circuit breaker must be secured to the pallet with shipping brackets.

Failure to follow these instructions can result in equipment damage.



3. Place the circuit breaker (**Figure 61, A**) onto the pallet (**B**).
4. For drawout circuit breakers, place the shipping brackets (**C**) on the circuit breaker. If shipping brackets are needed, consult the local field office. Bolt the shipping brackets to the circuit breaker. (Fixed-mounted circuit breakers use the mounting bracket installed on the circuit breaker as the shipping bracket.)
5. Secure the shipping brackets to pallet with four bolts, nuts and washers (**D**).

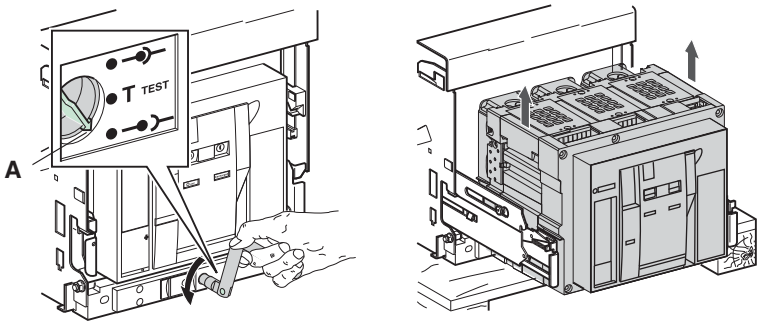
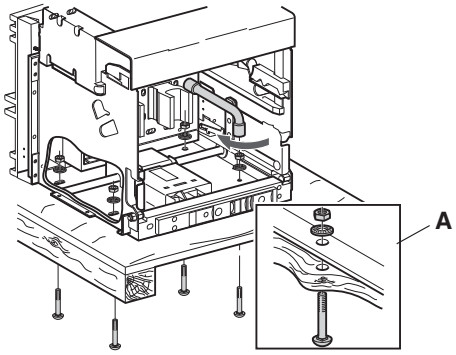
NOTICE



HAZARD OF EQUIPMENT DAMAGE

Cradle must be secured when installing or removing circuit breaker.

Failure to follow these instructions can result in equipment damage.



3. Rack the circuit breaker to the disconnected position (Figure 66, A) (refer to Drawout Circuit Breaker Disconnection, page 24).
4. Remove the circuit breaker following the instructions in “Circuit Breaker Removal” on page 27.

Hazard Categories and Special Symbols

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates a hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠CAUTION

CAUTION indicates a hazardous situation which, if not avoided, **can result in** minor or moderate injury.

NOTICE

NOTICE is used to address practices not related to physical injury. The safety alert symbol is not used with this signal word.

NOTE: Provides additional information to clarify or simplify a procedure.

Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

FCC Notice

This equipment has been tested and found to comply with the limits for a Class A digital device, pursuant to part 15 of the FCC Rules. These limits are designed to provide reasonable protection against harmful interference when the equipment is operated in a commercial environment. This equipment generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with the instruction manual, may cause harmful interference to radio communications. Operation of this equipment in a residential area is likely to cause harmful interference in which case the user will be required to correct the interference at his own expense. This Class A digital apparatus complies with Canadian ICES-003.

Section 1— Introduction

The service life of circuit breakers depends on proper application, correct installation, environmental conditions and preventive maintenance.

To maintain the device's operating and safety characteristics, Schneider Electric™ recommends that systematic checks and periodic maintenance be carried out by qualified personnel.

The standard generally used as a basis for field-testing requirements is the National Electrical Manufacturers Association® standard, NEMA AB 4, “Guidelines for Inspection and Preventive Maintenance of Molded Case Circuit Breakers Used in Commercial and Industrial Applications”. If additional information, assistance, or on-site service is required contact the local field sales office.

The inspection, preventive maintenance, and field-testing instructions provided in this document are intended for use with Masterpact™ NT and NW circuit breakers with the Micrologic™ electronic trip system. Please read this document carefully and keep it at hand. It provides detailed information on:

- the various types of maintenance required.
- what must receive maintenance.
- the risks involved if the component ceases to operate correctly.
- what is understood by the terms normal, improved and severe environment and operating conditions.
- the periodic preventive maintenance that should be carried out under normal environment and operating conditions as well as the level of competence required for the operations.
- the environment and operating conditions that accelerate device aging and the limits governing use of mechanical and electric accessories and subassemblies.
- the product guides available in order to maintain the device in proper operating condition.

This publication is not intended, nor is it adequate, to verify proper electrical performance of a circuit breaker that has been disassembled, modified, rebuilt, refurbished, or handled in any manner not intended or authorized by Schneider Electric.

Safety Precautions

1. Only qualified electrical workers with training and experience on low-voltage circuits should perform work described in these instructions. Workers must understand the hazards involved in working with or near low-voltage equipment. Such work should be performed only after reading this complete set of instructions.
2. Some inspections or procedures require that certain parts of the electrical system remain energized at hazardous voltage during the procedure. Observe all specific safety messages (Danger, Warning, Caution) throughout this manual.
3. Wear personal protective equipment, recognize potential hazard, and take adequate safety precautions when performing the procedures outlined in this manual.

Types of Maintenance

There are three types of maintenance discussed in this bulletin:

- Corrective
- Preventive
- Predictive

Corrective Maintenance

Corrective maintenance repairs items that are no longer functioning properly.

Incidents During System Startup

Many problems during system startup result from non-observance of the startup instructions or lack of knowledge concerning the equipment and/or switchgear procedures. Schneider Electric user guides contain instructions for operators or maintenance personnel on how to correct these problems.

- The list of the available user guides and data bulletins may be found at the end of this document.
- The PDF files for these documents may be downloaded from the www.schneider-electric.com site.

Incidents During Operation

Contact the local field sales office.

Preventive Maintenance

Preventive maintenance consists in carrying out, at predetermined intervals or according to prescribed criteria, checks intended to reduce the probability of a failure or deterioration in the operation of a system.

There are two types of preventive maintenance:

- Periodic maintenance
  For each type of product, maintenance recommendations are intended to maintain systems or their subassemblies in correct operating condition over the targeted service life, and must be carried out according to the time intervals stipulated in this document.
  Under no circumstances can Schneider Electric be held responsible for any damage caused by the failure of a device if the periodic checks were not carried out in accordance with the recommendations in this document.
- Conditional maintenance
  Conditional maintenance is performed when programmed alarms indicate that a predefined threshold has been reached. To that end, sensors must be installed on the switchgear and in the switchboard.
  To a certain extent, conditional maintenance reduces the recommended periodic maintenance that requires an annual shutdown of the installation. Conditional maintenance is the means to optimize installation maintenance. For more information on the possibilities offered by conditional maintenance, contact Schneider Electric Services.

 © 2012–2015 Schneider Electric All Rights Reserved

Predictive Maintenance

Predictive maintenance is based on the recording and analysis of system parameters to detect drift from the initial state and significant trends. Using predictive maintenance, the customer can anticipate the corrective action required to ensure equipment safety and continuity of service, and plan the action for the most convenient time.

Section 2— Preventive Maintenance

The tables in this section provide recommended preventive maintenance and time intervals. Recommendations are based on the operating conditions of the device.

Table 1 – Preventive Maintenance

Maintenance Type	Done By	Operating Conditions	Frequency
Type II	Certified customer employee	Normal	Every year
		Favorable	Every two years
		Severe	Twice a year
Type III	Certified customer employee	Normal	Every two years
		Favorable	Every four years
		Severe	Every year
Type IV	Schneider Electric Service	All	• Every five years • After tripping due to a short-time or instantaneous short-circuit • After five trips due to overloads.
Storage Check	Certified customer employee	All	After prolonged storage

Operating Conditions

Normal Conditions

Table 2 – Normal Operating and Environmental Conditions

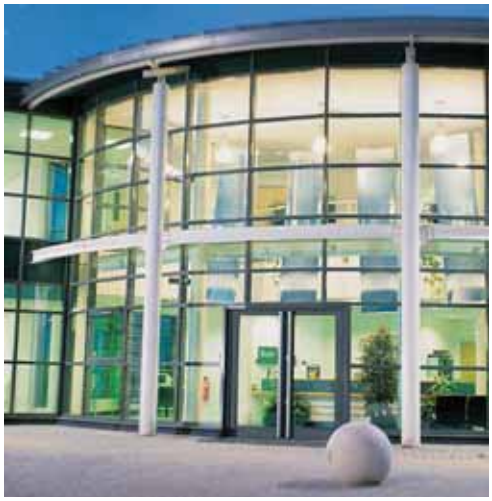
Temperature	Average annual temperature < 77°F (25 °C) outside the switchboard
Percent load	< 80% of I_n (sensor rating)
Harmonics	Harmonic current per phase < 30% of I_n (sensor rating)
Relative humidity	< 70%
Corrosive atmosphere	Device installed in environment category 3C1 or 3C2 (IEC 60721-3-3) in Tables 14 and 20
Salt environment	No salt mist
Dust	Low level Device protected in switchboard equipped with filters or ventilated IP54 (Nema 3) enclosure
Vibration	Permanent vibration < 0.2 g

Under these conditions, the maintenance that must be carried out every one, two or five years on Masterpact NT/NW subassemblies and the level of competence required on the part of service agents are described in the tables on pages 11, 12, and 13.

At the end of each five year period, the maintenance guide must be systematically repeated.

Beyond the above limits, the circuit breakers suffer accelerated aging that may result in malfunctions. For this reason, periodic checks must be carried out at shorter time intervals. On the other hand, when special efforts are made to improve the operating and environment conditions, the preventive-maintenance operations can be carried out less often.

© 2012–2015 Schneider Electric All Rights Reserved



Favorable Conditions

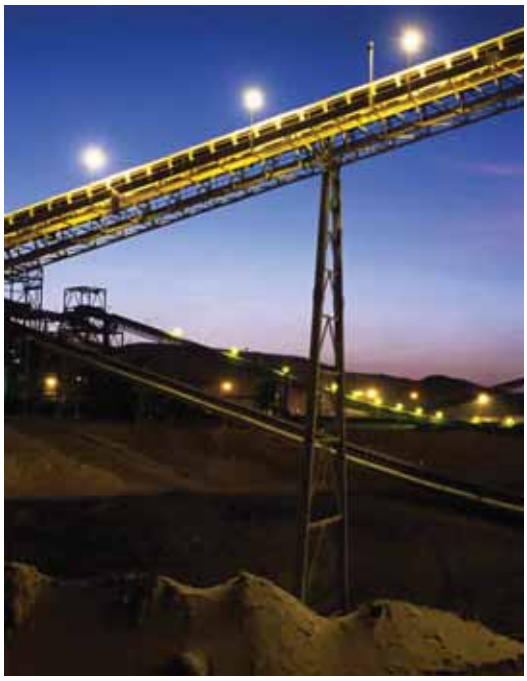
The time interval between Type II and Type III preventive maintenance can be doubled if **all** of the conditions presented below are met. The Type IV preventive maintenance program is still recommended for every 5th year.

Table 3 – Favorable Operating and Environmental Conditions

Protection	Device is protected from environmental conditions
Temperature	Average annual temperature < 77°F (25 °C) outside the switchboard. The device is installed in an air-conditioned room or in a ventilated enclosure
Percent Load	< 50% of I_n (sensor rating)
Relative Humidity	< 50%
Corrosive Atmosphere	Device installed in a protected room (air is conditioned and purified)
Salt Environment	None
Dust	Negligible Device protected in switchboard equipped with filters or ventilated IP54 (Nema 3) enclosure
Vibration	None

Figure 1 – Favorable Conditions

 © 2012–2015 Schneider Electric All Rights Reserved



Severe Conditions

The time interval between two preventive maintenance visits must be reduced by half **if any of the conditions** presented below are present unless the device is protected from the condition.

Table 4 – Severe Operating and Environmental Conditions

Temperature (annual average)	Average annual temperature between 95 °F and 113 °F [35 °C and 45 °C] around the switchboard
Percent Load	> 80% of I_n (sensor rating)
Relative Humidity	> 80%
Corrosive Atmosphere	Device installed in environment category 3C3 or 3C4 without any particular protection, see Table 14
Salt Environment	Installation < 6.2 miles (10 kilometers) from seaside and device without any particular protection
Dust	High level of dust and equipment is not protected See Table 13
Vibration	Continuous vibrations between 0.2 and 0.5 g

Preventive Maintenance Operations

Level II Preventive Maintenance

It is recommended that Level II preventive maintenance be done every year.

Level II maintenance consists of minor preventive maintenance such as greasing and operating checks, as well as repairs by standard exchange of certain assemblies, carried out by a certified customer employee according to the manufacturer maintenance instructions. See the instruction bulletin and user guides for procedures. See Section 4 for what must be maintained.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E, CSA Z462, or NOM-029-STPS.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Disconnect all power sources before performing maintenance inspections. Assume that all circuits are live until they are completely de-energized, tested, grounded and tagged. Consider all sources of power, including the possibility of backfeeding and control power.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Level III Preventive Maintenance

It is recommended that Level III preventive maintenance be done every two years.

Level III maintenance consists of preventive maintenance such as general adjustments, troubleshooting and diagnosis of breakdowns, repairs by exchange of components or functional parts, minor mechanical repairs, carried out by a qualified customer technician using the tools specified in the manufacturer maintenance instructions. See the instruction bulletin and user guides for procedures.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E, CSA Z462, or NOM-029-STPS.

Level IV Preventive Maintenance

It is recommended that Level IV preventive maintenance be done every five years.

Level IV maintenance consists of manufacturer diagnostic and replacement of components by the Schneider Electric Services support department. See the instruction bulletin and user guides for procedures.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Maintenance After Storage

Storage Conditions

Devices must be stored in a dry, ventilated area, protected from rain, water and chemical agents. They must be well protected against dust, rubble, paint, etc.

If storage is for an extended period, the following storage conditions are necessary:

- relative humidity in the room must be maintained below 70%.
- circuit breakers with trip units without LCD displays may be stored in the original packaging at temperatures between -40 °F to +185 °F (-40 °C to +85 °C).
- circuit breakers with trip units with LCD displays may be stored in the original packaging at temperatures between -13 °F to +185 °F (-25 °C to +85 °C).
- devices must be stored in the open (OFF) position with the charging springs discharged.

Checks and Maintenance

After extended storage, the checks below must be carried out before installation to ensure correct device operation.

Storage ≤ 2 years

Run the Level II and III second year program on the subassemblies below:

- mechanism
- trip unit
- device and cradle locking
- cradle

Storage > 2 years

Run the Level III and IV fifth year diagnostic program on the subassemblies below:

- mechanism
- control accessories
- trip unit
- device and cradle locking
- cradle

If the devices were stored under severe conditions (high temperature, corrosive atmosphere), it is necessary to:

- check the surface condition of the metal parts (zinc) and the copper parts (silver coatings [Ag] or tinning [Sn]).
- check the greasing for the device and cradle.
- regrease the clusters and check primary contacts.

Section 3— Accelerated Aging

Causes of Accelerated Aging

A switchboard and the switchgear age, whether they are in operation or not. Aging is due primarily to the influence of the environment and the operating conditions.

Influence of the environment

A device placed in a given environment is subjected to its effects.

The main environmental factors that accelerate device aging are:

- temperature
- percent load
- relative humidity
- salt environment
- current harmonics
- dust
- corrosive atmospheres.

Table 8 – Ambient Temperature (Outside the Switchboard)[1]

Influence	Appearance	Consequences
The mechanical characteristics of plastic parts (insulation, case) are increasingly deteriorated by temperature the higher it rises.	Change in color	Breaking of parts leading to failure of functions
Hardening of grease Elimination of grease on primary contact clusters	Change in color and viscosity Caramel color of grease on clusters	Device cannot be operated Increase of racking forces exerted on clusters
Deterioration of insulating varnishes on coils	Burning smell.	Failure of coils (CT, MN, MX, XF, MCH, electrical reset).
Hardening of glues on labels	Visual	Loss of labels
Deterioration of electronic components	Modified display of LCDs	Loss of display Nuisance tripping or no tripping
Deterioration of opto-electronic devices and SCRs.	Not identifiable	Possible transmission of erroneous orders
Loss of battery backup power	Not identifiable	Fault indications not displayed
Temperature Thresholds in °C		
≤ 77°F (25°C)	78–95°F (26–35°C)	96–113°F (36–45°C)
Optimum operating conditions	An 18°F (10°C) increase in the ambient temperature is equivalent to a 5% increase in the percent load	A 35°F (20°C) increase in the ambient temperature is equivalent to a 10% increase in the percent load
Recommendation		
Preventive maintenance		
Implement the standard program	Carry out more frequent periodic checks (see page 8)	Carry out more frequent periodic checks (see page 8)
Installation		
No particular precautions required	No particular precautions required	Install forced-air ventilation in the switchboard or air-conditioning for the electrical room

[1] The ambient temperature affects the device temperature, which is affected by the percent load. Major variations in temperature (greater than 54°F [30°C]) cause both mechanical stresses (thermal expansion) and condensation that can accelerate aging.

© 2012–2015 Schneider Electric All Rights Reserved

Table 9 – Percent Load (Sensor Rating I_n)[1]

Influence	Appearance	Consequences
Aging of plastic insulation	Change in color of insulation	Breaking of parts leading to failure of functions
Aging of grease	Change in color and viscosity	Increase in mechanical friction
Aging of electronic components	Modified display of LCDs	A 10°C increase (i.e. a 90% load) cuts the service life of components by approximately half.
Deterioration of characteristics: • steel springs (above 100°C) • stainless steel springs (above 200°C)	Rupture	Non-operation of mechanism

Thresholds				
≤ 80, 24/24 hours	≤ 90%, 8/24 hours	≤ 90%, 24/24 hours	I_n, 8/24 hours	I_n, 24/24 hours
Maximum percent load generally taken into account in sizing the installation. At this percent load, temperature rise is reduced approximately 40% with respect to a 100 percent load.	At this percent load, temperature rise is reduced only 20%. Heating and cooling cycles impact on the mechanical junctions of the power circuit.	The thermal stress for continuous operation is three times higher than in the previous case, but the absence of thermal cycles slows aging of the electromechanical components.	Between 90 and 100%, temperature rise is close to its maximum value. Heating and cooling cycles impact on the mechanical junctions of the power circuit, with major impact on aging.	Between 90 and 100%, temperature rise is close to its maximum value. This situation has a major impact on aging.
Recommendations				
Preventive Maintenance				
Implement the standard program	Increase frequency of periodic checks (see page 8)	Preventive maintenance is difficult due to the continuous process	Increase frequency of periodic checks (see page 8)	Preventive maintenance is difficult due to the continuous process. Plan more frequent periodic checks.
Installation				
			Provide ventilation for switchboard	Spread the load over other circuit breakers Install a device with a higher rating.

[1] The percent load affects the device temperature, which is itself affected by the ambient temperature.

Table 10 – Relative Humidity

Influence	Appearance	Consequences
Corrosion of metal surfaces that is accelerated when a pollutant is present (corrosive gas, salt, chlorine, etc.)	Appearance of: • red rust on iron • white rust on zinc • blue deposit on copper • black deposit on silver	Increase in friction Risk of mechanical rupture resulting in non-operation of mechanisms Increase in contact resistance (clusters and main contacts)
Deterioration of dielectric qualities of plastics	White traces on case	Risk of a reduction in insulation
Deterioration of electronic components, in particular printed circuit boards and silver-coated components. This phenomenon is worsened by the presence of H_2S corrosive gas (hydrogen sulphide).	Not visible Appearance of dendrites on electronic boards	Short-circuiting of circuits resulting in non-operation of control-unit protection, measurement, indication and communication functions.
Deterioration of electronic components, in particular non-varnished copper circuits.	Not visible Erosion of copper tracks Oxidation of metal connectors of components and metal cases Oxidation of connectors of integrated-circuits mounted on supports	Failure due to short-circuit or open circuit Rupture of component connectors along case Poor contact with integrated-circuit supports
Degradation of opto-electronic components.		Failure of data transmission.
Thresholds in%		
< 70%	70 to 85%	> 85%
Level of relative humidity generally found in continental and temperate zones. The level is generally lower in switchboards due to the internal temperature rise. No significant deterioration is noted at this level.	Level of relative humidity generally found in zones close to water. Possible appearance of condensation on cold parts and accelerated rusting.	Level of relative humidity generally found in tropical zones and certain factories (e.g. paper mills). Increased risk of condensation and rust resulting in difficulties to disconnect devices, risk of non-opening or non-closing.
Recommendation		
Preventive Maintenance		
Preventive maintenance	Carry out more frequent periodic checks (see page 8) Measurement of insulation is advised every 5 years	Carry out more frequent periodic checks (see page 8) Inspect for rust on metal parts Measurement of insulation is imperative every two years
Installation		
No particular precautions required		Install heating elements in the switchboard

Table 11 – Salt Environment

Influence	Appearance	Consequences
Corrosion of metal parts	Appearance of: • white rust on zinc coatings • red rust on steel	Increase in friction. Freezing of mechanism Broken springs. Blocking of cores of MX / XF / MN control accessories.
Risk of salt deposits on electronic circuit when thick salt mists occur.	Appearance of salt bridges on electronic boards.	Failure of electronic systems due to short-circuiting of circuits, particularly non-varnished circuits.
Risk of conducting salt deposits on the device when thick salt mists occur.	White deposit	Deterioration of device dielectric withstand resulting in risk of phase-to-frame short circuit and a phase-to-phase short circuit if an overload occurs.
Thresholds		
No salt mist	Moderate salt mist < 6 miles (10 km)from seaside	Significant salt mist < 0.6 miles (1 km) from seaside
No influence.	Moderate aging of switchgear.	Rapid aging of exposed switchgear. On average, service life is divided by a factor of three for non-protected devices.
Recommendation		
Preventive Maintenance		
Implement the standard program.	Carry out more frequent periodic checks (see page 8).	Carry out more frequent periodic checks (see page 8). Test the dielectric withstand every two years.

Operating Conditions

Operating conditions directly affect the service life of switchgear due to the limited electrical and mechanical endurance levels of the various subassemblies. Operating conditions include:

- vibrations,
- the number of operating cycles,
- the interrupted currents.

Table 16 – Vibrations

Influence	Appearance	Consequences	
Premature deterioration of contact surfaces (clusters and main contacts).	Not identifiable.	Increased device temperature rise.	
Loosening of bolted assemblies.	Not identifiable.	Increase in mechanical clearance.	
Wear of mechanical parts.	Not identifiable.	Broken springs. Increase in mechanical clearance between parts.	
Appearance of fretting corrosion on auxiliary connections.	Not identifiable.	Erroneous information or loss of continuity in data or supply, excessive temperature rise.	
Breaking of connectors on large electronic components (e.g. large capacitors).	Not identifiable.	Failure of protection function.

Table 17 – Number of Operating Cycles

Influence		Consequences
The number of operating cycles depends directly on the electrical and mechanical endurance of the device.		Device service life depends on the daily number of operating cycles.
Device Service Life (depends on the daily number of operating cycles)		
≤ 30 cycles per month	≤ 60 cycles per month	≤ 120 cycles per month
Corresponds to one cycle per day. For a device endurance of 10,000 cycles and an interrupted current of less than 0.4 I_n, the service life is 30 years.	Corresponds to two cycles per day. For a device endurance of 10,000 cycles and an interrupted current of less than 0.4 I_n, the service life is 15 years.	Corresponds to four cycles per day. For a device endurance of 10,000 cycles and an interrupted current of less than 0.4 I_n, the service life is 10 years.

Table 18 – Interrupted Current

Influence	Appearance	Consequences
Wear of fixed and moving contacts.	Deterioration of contacts.	Beyond the electrical-endurance limit, device temperature rise increases due to the greater contact resistance and a reduction in the pressure of contacts.
Wear of the arc chutes (insulating materials, separators).	Deterioration of insulation.	Beyond the electrical-endurance limit, the insulation separators). (input/output and between phases) is reduced, which results in a reduction of device suitability for isolation and can create an unsafe condition.
Thresholds		
≤ I_n (Sensor Rating)	> I_n to ≤ 4 I_n (Sensor Rating)	> 4I_n to ≤ 8 I_n (Sensor Rating)
This level of interrupted current corresponds to the mechanical durability (see Mechanical endurance).	This level of interrupted current corresponds to expected levels of short time events.	This level of interrupted current corresponds to the severe short circuit events. Requires inspection of contacts and arc chutes.

Molded Case

The case is an essential element in the circuit breaker. First, it provides a number of safety functions by:

- providing functional insulation between the phases themselves and between the phases and the exposed conductive parts in order to resist transient overvoltages caused by the distribution system
- providing a barrier, preventing direct user contact with live parts
- protecting against the effects of electrical arcs and overpressures caused by short-circuits.

Second, it serves to support the operating mechanism as well as the mechanical and electrical accessories of the circuit breaker.

On the case, there should be:

- no traces of grime (grease), excessive dust or condensation which all reduce insulation
- no signs of burns or cracks which could weaken the case and thus its capacity to withstand short-circuits.

Preventive maintenance for cases consists of:

- a visual inspection of its condition and cleaning with a dry cloth or a vacuum cleaner. All cleaning products with solvents are strictly forbidden.
- Measuring the insulation every five years and following trips due to a short-circuit.

Replace the circuit breaker if there are signs of burns or cracks.

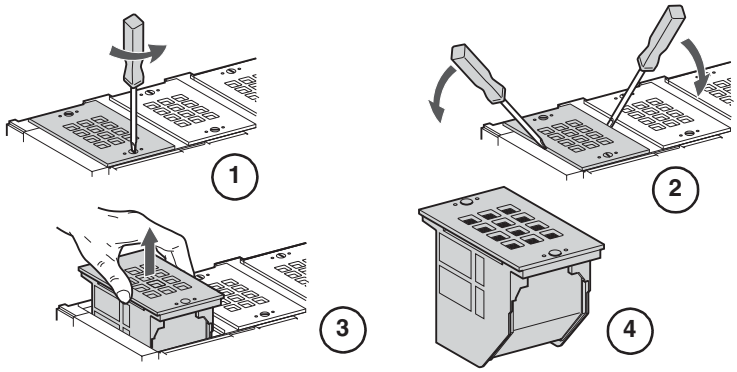
Arc Chutes

During a short-circuit, the arc chute serves to extinguish the arc and to absorb the high level of energy along the entire path of the short-circuit. It also contributes to arc extinction under rated current conditions. An arc chute that is not in good condition may not be capable of fully clearing the short-circuit and ultimately result in the destruction of the circuit breaker.



The arc chutes must be regularly checked. The fins of the arc chutes may be blackened (due to the gases produced at I_n) but must not be significantly damaged. What is more, the filters must not be blocked to avoid internal overpressures. Use a vacuum cleaner rather than a cloth to remove dust from the outside of the arc chutes.

Arc Chamber Maintenance

1. Unscrew the mounting screws.
2. Use screwdrivers to lift arc chamber from circuit breaker.
3. Remove arc chamber.
4. Inspect arc chamber. Check that arc chamber body is not broken and that the plates are intact and not significantly burned or melted.

If necessary, replace arc chamber.

Figure 8 – Arc Chamber Maintenance

Main Contacts

The contacts make and break the current under normal conditions (rated current for the installation) and under exceptional conditions (overloads and short-circuits). The contacts are eroded by the many opening and closing cycles and can be particularly deteriorated by short-circuit currents. Worn contacts may result in abnormal temperature rise and accelerate device aging.

It is imperative to remove the arc chutes and visually check contact wear at least once a year and following each short-circuit event.

The contact-wear indicators constitute an absolute minimum value that must not be overrun.

To plan and reduce the number of shutdowns, an electronic wear counter is available with the Micrologic P and H. A visual check is required when the counter reaches 100. When the counter reaches 300, the contacts are worn out and must be replaced.

Main Contact Maintenance

1. Remove the arc chambers.
2. Close the circuit breaker and check the condition of the contacts.

If contacts are worn, the circuit breaker block assembly must be replaced.

Device and Cradle Mechanisms

Mechanical operation of the circuit breaker may be hindered by dust, vibration, aggressive atmospheres, no greasing, or excessive greasing. Operating safety is ensured by dusting and general cleaning, proper greasing, and regular opening and closing of the circuit breaker.

Dusting

Dusting is best carried out using a vacuum cleaner.

Cleaning

Cleaning should be carried out using a cloth or brush that is perfectly clean and dry, without using any solvents, avoiding greased parts except for grease on electrical contacts. Application of products under pressure or containing solvents (trichloroethane, trichloroethylene, WD40®) is strictly forbidden.

The main problems of products under pressure are the following:

- it may be impossible to regrease inaccessible lubrication points (which are greased for the life of the product)
- corrosion of points that are not regreased
- damage caused by the pressure
- risk of temperature rise due to the presence of an insulating solvent in the contact zones
- elimination of special protection
- deterioration of plastic materials.

Greasing

This operation is carried out after cleaning on certain mechanical parts as described in the maintenance procedures, using the various greases recommended by Schneider Electric. Grease must not be over applied because the excess, if mixed with dust, may result in mechanism malfunctions. Generally speaking, under normal operating conditions, the pole-operating mechanism does not require any regreasing as it is greased for the life of the product.

- The clusters and disconnecting-contacts must be greased according to the defined intervals using the greases indicated by Schneider Electric.
- The main contacts must not be greased.

Operating Cycles

The need for continuity of service in an installation generally means that power circuit breakers are rarely operated. While an excessive number of operating cycles accelerates device aging, it is also true that a lack of operation over a long period can result in mechanical malfunctions. Regular operation is required to maintain the normal performance level of each part involved in the opening and closing cycles.

In installations where power circuit breakers are used in source changeover systems, it is advised to periodically operate the circuit breaker for the alternate source.

Auxiliary Circuits

Control Accessories

MX and XF shunt releases are respectively used to remotely open and close the circuit breaker using an electrical order or through a communication network.

The MN undervoltage release is used to break the power circuit if the distribution system voltage drops or fails.

Communicating MX and XF releases and MN releases are continuously supplied and their internal electronic components may suffer accelerated aging if there is temperature rise in the circuit breaker.

Preventive maintenance consists of periodically checking operation at minimum values.

Auxiliary Wiring

Auxiliary wiring is used to transmit orders to the various control devices and to transmit status condition information. Incorrect connections or damaged insulation may result in either non-operation of the circuit breaker or nuisance tripping.

Auxiliary wiring must be regularly checked and replaced as needed, particularly if there are vibrations, high ambient temperatures or corrosive atmospheres.

Indication Contacts

The contacts indicating the status of the circuit-breaker (ON / OFF), of the cradle (CE, CD, CT), a trip due to an electrical fault (SDE), or that the circuit breaker is ready to close (PF) provide the operator with the status information required to react correspondingly. Any incorrect indications may result in erroneous device operation. Contact failure (wear, loose connections) may result from vibrations, corrosion or abnormal temperature rise and preventive maintenance must ensure that contacts correctly conduct or isolate according to their positions.

Spring Charging Motor

The spring charging motor (MCH) automatically recharges the operating-mechanism springs as soon as the circuit breaker is closed. The spring charging motor makes it possible to instantaneously reclose the device following an opening. This function may be indispensable for safety reasons. The charging lever serves simply as a backup means if the auxiliary voltage fails. Periodic checks on the spring charging motor operation and the charging time are required to ensure the device function.

© 2012–2015 Schneider Electric All Rights Reserved

Electronic Trip Unit

If an electric fault occurs in the installation, the electronic trip unit detects the fault and orders the circuit breaker to open.

Electronic components and circuit boards are sensitive to the environment (ambient temperature, humid and corrosive atmospheres) and to severe operating conditions (magnetic fields, vibrations, etc.). To ensure correct operation, it is necessary to periodically check:

- the chain of action resulting in a trip
- the response time as a function of the level of the fault current.

Use HHTK or FFTK test kits for secondary injection testing or test with primary injection.

Communication Module and Accessories

I/O Module IFM Module

IFE Module

Using the communication bus, the communication option transmits data to a remote site for use by various departments (maintenance, management, production, etc.).

A break in the transmission of data can result in:

- production losses due to unawareness concerning the status of a circuit breaker
- financial losses due to incorrect system management, diagnostic errors, etc.

Periodic checks on the orders (read, write, commands) transmitted by the communication bus are required to maintain a high degree of reliability and confidence in the communication system.

Connections

The connections between the various distribution systems in a switchboard (busbars, cables) and the switchgear are a major source of heat loss. Incorrect tightening may lead to thermal runaway which in turn can provoke damage to the device, the cable insulation, or result in a short-circuit and/or a fire. This type of malfunction is often due to disregard for installation requirements during switchboard assembly.

NOTE: Connections must never use different materials (copper/aluminium).

© 2012–2015 Schneider Electric All Rights Reserved

Fixed Circuit Breakers

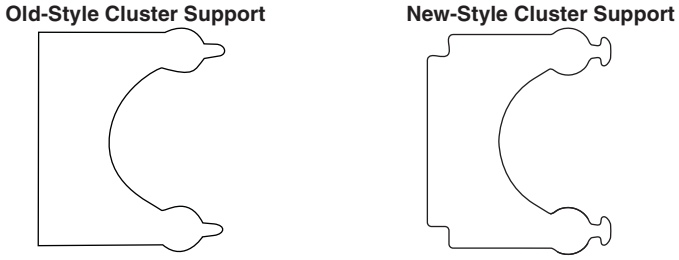
Fixed circuit breaker connections use lugs or bars. When made in compliance with Schneider Electric recommendations (tightening torque, hardware, and contact washer), this type of connection does not require any particular maintenance.

Otherwise, regularly check the temperature-rise points. If there is a change in color of copper or tinning:

- dismantle the connections
- clean and scrape the contact surfaces
- then reassemble the connections using new hardware.

Check the terminals.

Drawout Circuit Breakers (Cradle)



Drawout circuit breaker connections are made up of two parts, the clusters and disconnecting contacts. This type of connection is critical and requires periodic cleaning in compliance with the described procedures. The grease facilitates the connection between the clusters and the disconnecting contacts and avoids damaging the silver-coated surface by reducing the racking-in friction.

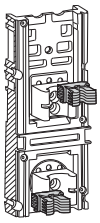
In sulphurous (corrosive) atmospheres (H2S/SO2), it is necessary to implement the cleaning procedure using the Thiourea solution, with mandatory regreasing using fluorous grease (such as Pyratex® EP). This type of grease protects the silver and copper-coated contacts against sulphurizing. Because silver or copper sulphide is insulating it creates an increase in the contact resistance and thus greater temperature rise. The grease breaks down over time and it is therefore necessary to replace it regularly.

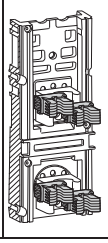
Cluster Inspection and Lubrication (Masterpact NW Drawout Circuit Breakers Only)

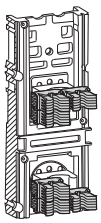
1. If the circuit breaker is equipped with cluster retainers, remove the retainers as necessary to inspect the clusters and cluster supports.
2. If the circuit breaker is equipped with ArcBlok or cluster shields, use the S47542 cluster tool to remove the clusters for inspection.

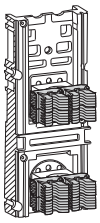
Figure 9 – Cluster Support Profiles

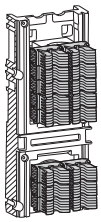
Make sure clusters are installed properly as shown in Table 21.

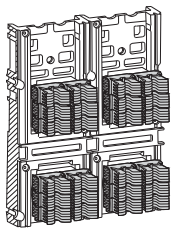












3. Visually inspect clusters for wear or signs of damage such as:
   - — discolored areas
   - — visible copper on fingers
   - — cracked or broken springs
   - — missing clusters
   - — not aligned with other cluster (indicates spring damage)
4. Visually inspect clusters for wear.

 © 2012–2015 Schneider Electric All Rights Reserved

5. For circuit breakers with cluster retainers: check that all clusters have cluster retainers.

NOTE: Circuit breakers with cluster shields or ArcBlok shields do not need the cluster retention kits. Do not attempt to install the cluster retention kits on those circuit breakers.

NOTICE

HAZARD OF EQUIPMENT DAMAGE

- If clusters are removed for any reason, clusters must be installed using cluster positioning tool S47542.
- Lubricate clusters as shown in Cluster Lubrication on page 37.
- Do not install anything in the cluster jaw except 3/8 in. (9.5 mm) wide bus bar or Cluster Reset Tool, catalog number CLUSRETOOL.

Failure to follow these instructions can result in equipment damage.

If Masterpact NW clusters are worn or damaged, new clusters must be installed using cluster positioning tool S47542.

— Replace worn or damaged clusters on all cluster configurations.

— Install new clusters (Figure 10, A) using cluster positioning tool S47542 (B).

Figure 10 – Cluster Replacement

If clusters and cluster supports are not damaged and the circuit breaker is not equipped with a cluster shield or ArcBlok Shield, you can continue to use the cluster retainer kits. If necessary, retrofit using new cluster supports, finger clusters and cluster shields/ArcBlok shields.

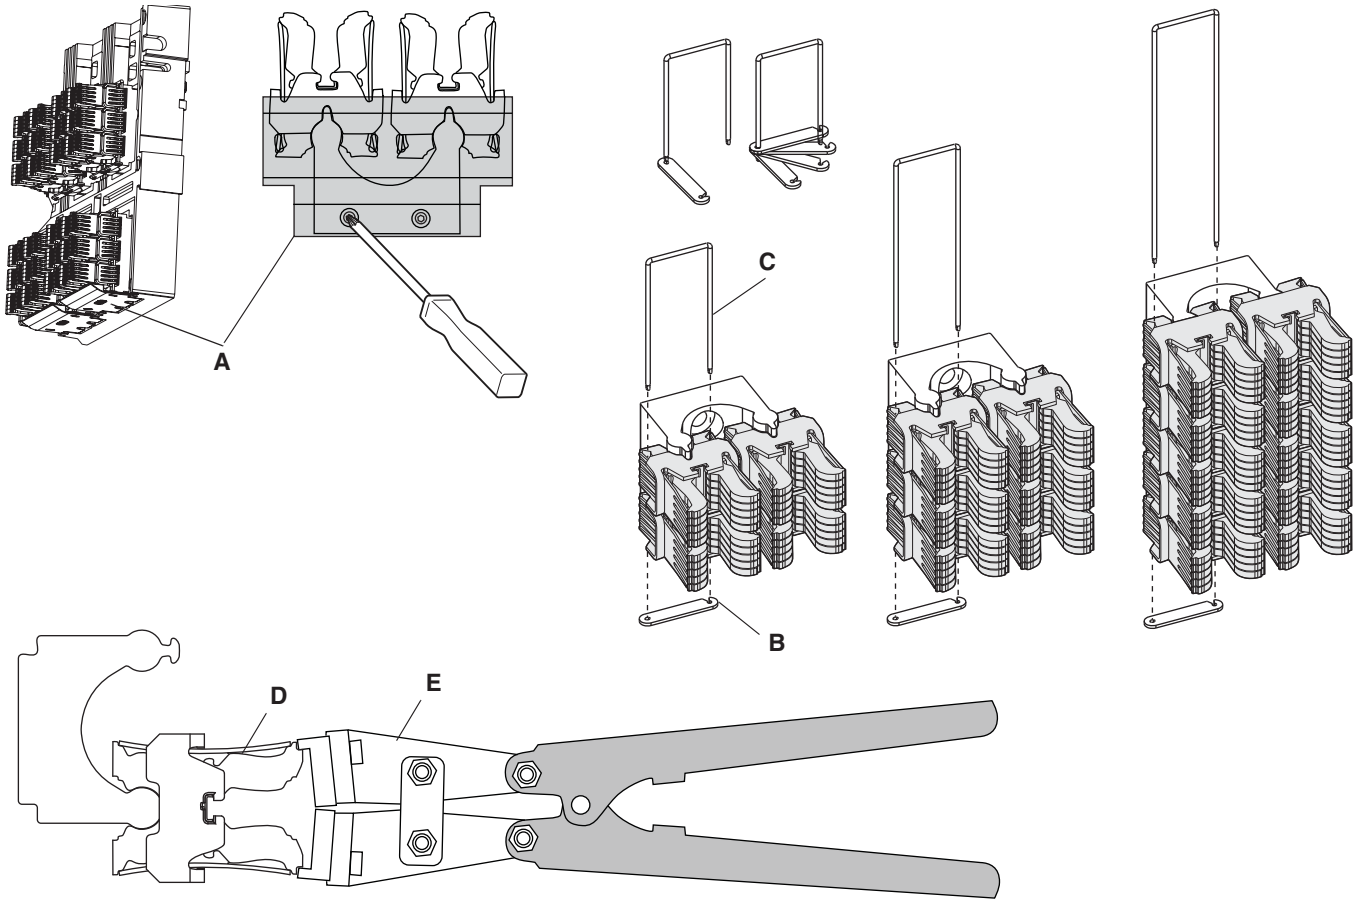
⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH



Install the correct cluster retainer identified by color depending on circuit breaker size and type. See Table 23.

Failure to follow these instructions will result in death or serious injury.

NOTE: Cluster retainer clip cannot be reused. Use new cluster retainer clip, part number CRCLIP.

1. Replace worn or damaged clusters on all cluster configurations except lower clusters on 16 and 24 cluster configurations.
   a. Remove lower connector plate (Figure 11, A), if present. Retain plate, screws and washers.
   b. Remove cluster retainer clip (B) and cluster retainer (C), if equipped. Discard cluster retainer clip. Remove worn or damaged clusters.
   c. Install new clusters (D) using cluster positioning tool S47542 (E).
   d. Secure clusters using cluster retainer (C) and new cluster retainer clip (B). See Table 23 for correct cluster retention kit and cluster retainer color.
   e. Replace lower connector plate (A), if previously removed. Secure using previously-retained screws and washers. Torque screws to 17.7 lb-in. (2 N•m).

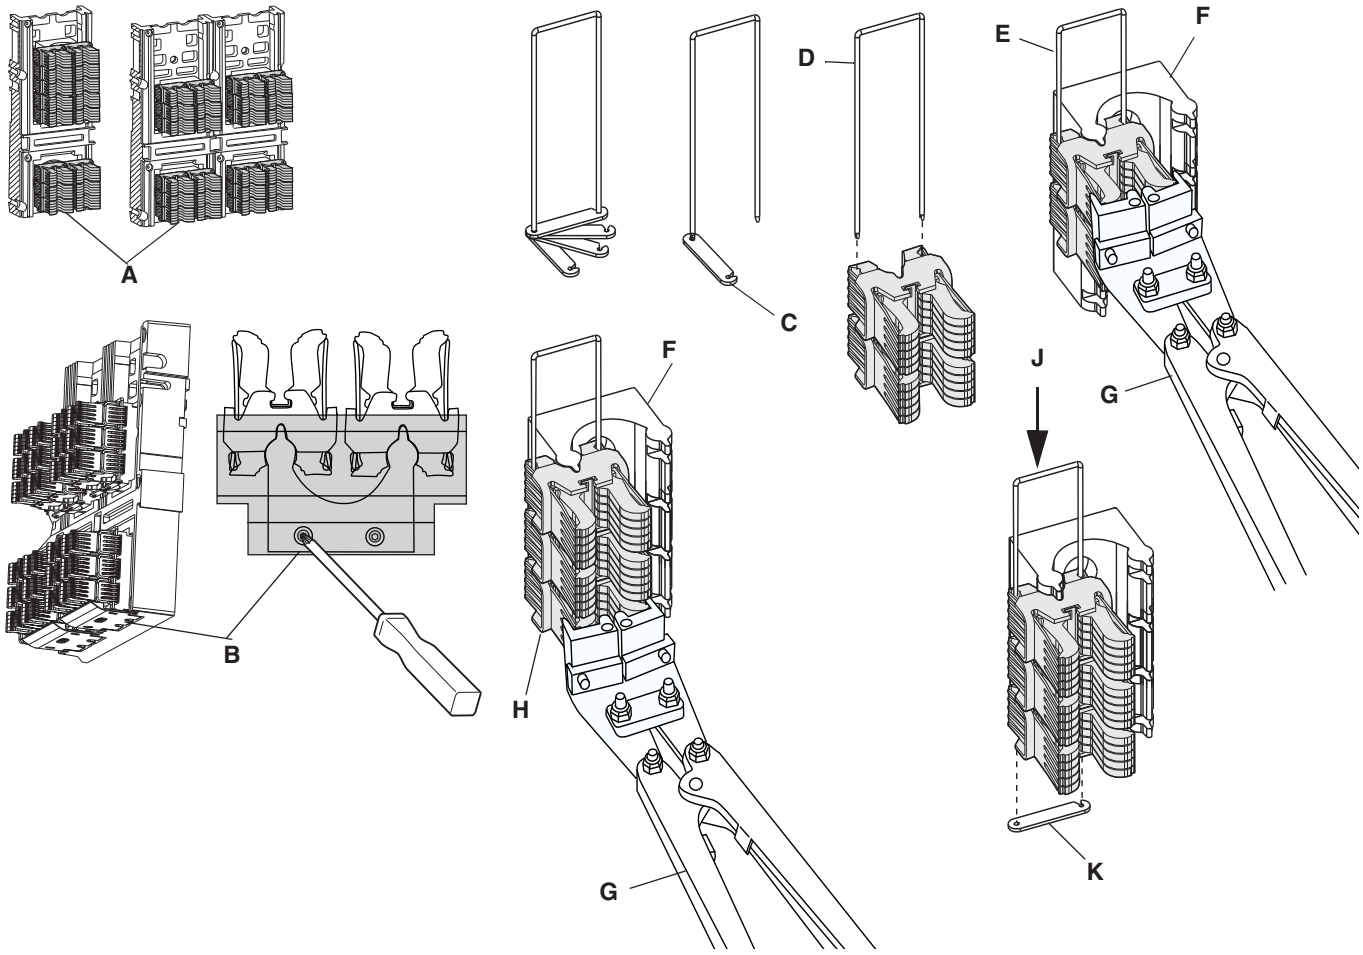
HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH



Install the correct cluster retainer identified by color depending on circuit breaker size and type. See Table 23.

Failure to follow these instructions will result in death or serious injury.

2. Replace worn or damaged clusters on lower set of clusters on 16 and 24 cluster configurations (Figure 12, A):
   a. Remove lower connector plate (B), if present. Retain plate, screws and washers.
   b. Remove cluster retainer clip (C) and cluster retainer (D), if equipped. Discard cluster retainer clip. Remove all clusters, discard worn or damaged clusters.
   c. Slide cluster retainer (D) through two clusters until bottom of cluster retainer is even with bottom of lower cluster. See Table 23 for correct cluster retainer kit and color.
   d. Install the two clusters and cluster retainer (E) on top two notches of cluster support (F) using cluster positioning tool S47542 (G).

Cluster Lubrication

NOTICE
HAZARD OF EQUIPMENT DAMAGE Inspect the cluster for lubrication when the circuit breaker is removed from the cradle. **Failure to follow these instructions can result in equipment damage.**

Use grease kit (catalog number S48899) to lubricate cluster jaws as shown in Figure 13.

NOTE: Remove any existing grease from cluster assembly before applying new grease to clusters.

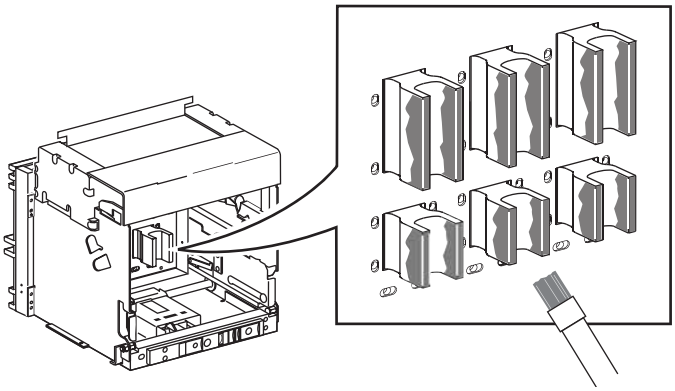
Cradle Stab Lubrication

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E, CSA Z462, or NOM-029-STPS.
- This equipment must be installed and serviced only by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.



Failure to follow these instructions will result in death or serious injury.

The cradle stabs must be inspected and lubricated when the cradle is first installed and again during maintenance periods after all power has been disconnected.

Confirm that both sides of stab are coated with lubricant. If necessary, use grease kit (catalog number S48899) to lubricate stab.

NOTE: Remove any existing grease from cradle stabs before applying new grease to them.

Section 6— Testing

Procedures

Visual Inspections During Operation

While circuit breaker is energized:

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E, CSA Z462, or NOM-029-STPS.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Take precautions to ensure that no accidental contact is made with live components during this check.

Failure to follow these instructions will result in death or serious injury.

1. Verify circuit breaker application and rating.

   Make sure that the circuit breaker is properly applied within labeled voltage, ampere rating, maximum current interrupting ratings and to Company recommendations. Compare the circuit breaker faceplate data to the installation drawings. Verify trip unit settings on Micrologic electronic-trip circuit breakers with the coordination study. After completing inspection and maintenance procedures, insure that all trip unit settings for all functions are set according to the coordination study.

2. Check for overheating while equipment is energized.

   While the circuit breaker is normally operating, under load and at operating temperature, check the exposed, accessible, insulated face of the circuit breaker and adjacent dead front surfaces of the enclosure for overheating. To do this, use an infrared temperature probe to check the temperature. If the temperature exceeds 140°F (60°C), the cause should be investigated.

   Allow initially energized circuit breaker at least three hours to reach operating temperature. Compare the surface temperature of individual circuit breakers with the surface temperature of other circuit breakers in the installation. Circuit breaker surface temperatures vary according to loading, position in the panelboard and ambient temperature. If the surface temperature of a circuit breaker is considerably higher than adjacent circuit breakers, the cause should be investigated.

   Thermographic inspection methods may also be used to evaluate overheating with equipment energized (see Thermographic Inspection, page 44).

3. Check for cracks in the circuit breaker case.

   Any circuit breaker with a cracked case should be replaced because its ability to withstand short-circuit interruption stresses is reduced.

4. Inspect the enclosure.

   The enclosure should be clean and dry. All covers and trim pieces should be in place.

Thermographic Inspection

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Only qualified electrical workers with training and experience on low-voltage circuits should perform thermographic inspections. These workers must understand the hazards involved in working with or near low-voltage equipment. Perform such work only after reading this complete set of instructions.

Failure to follow these instructions will result in death or serious injury.

Infrared thermographic inspection techniques may be useful in evaluating the operating condition of circuit breakers and terminations. Comparison to stored infrared thermographic images may be useful for the preventive maintenance of circuit breakers and end-use equipment. The actual amount of heat emitted is a function of both load current and ambient conditions. Interpretation of infrared survey requires experience and training in this type of inspection.

Allow initially energized circuit breakers at least three hours to reach operating temperature. Compare the thermographic images of individual circuit breakers to previously stored images of the same circuit breakers.

Performance Tests

Do the performance tests in the order given to maximize the accuracy of the test results.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E, CSA Z462, or NOM-029-STPS.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- Do not touch the circuit breaker terminals or the test leads while the circuit breaker is being tested.

Failure to follow these instructions will result in death or serious injury.

NOTE: Never do the contact resistance test before doing the instantaneous primary injection testing. The primary injection testing will ensure the contacts are clear of resistive films, oxidation and foreign material.

The following tests are intended to verify that a circuit breaker is operating properly. Precisely controlled factory testing conditions are used to establish the characteristic trip curves. If field test results fall outside the characteristic trip curve tolerance band, carefully evaluate the test conditions and methods for accuracy.

 © 2012–2015 Schneider Electric All Rights Reserved

When questionable conditions or results are observed during inspection and performance tests, consult the local field sales office. Circuit breakers with accessories or factory modifications may require special investigation. If it is necessary to return a circuit breaker to the manufacturing facility, use proper packaging and packing materials to avoid shipping damage.

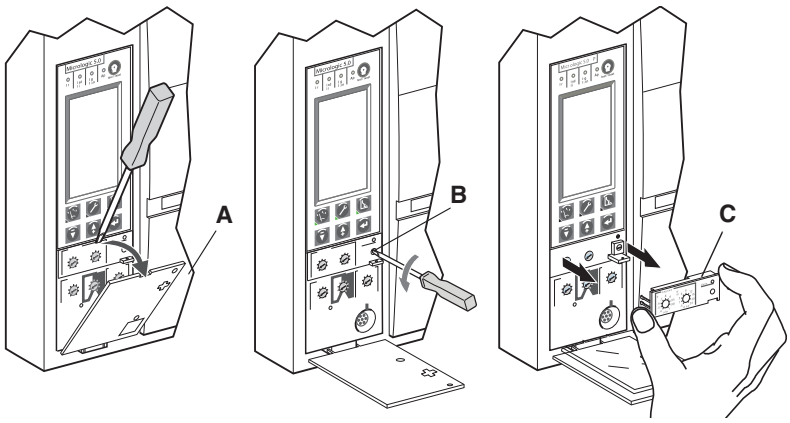
Dielectric Testing Masterpact Circuit Breakers with Micrologic P or H Trip Systems

NOTICE

HAZARD OF EQUIPMENT DAMAGE

- Dielectric tests (high potential, insulation resistance, or Megger tests) may damage Micrologic P and H trip units.
- Remove rating plug from trip unit prior to testing.
- Replace trip unit if rating plug was not removed during tests or if trip unit was exposed to more than 700 Vac.

Failure to follow these instructions can result in equipment damage.



Dielectric tests (high potential, insulation resistance or Megger tests) are used to ensure the proper isolation and insulation between phases and between each phase and ground. The equipment used to conduct these tests creates a high-potential voltage (thousands of volts) to verify dielectric or insulation integrity.

The rating plug on Micrologic P and H trip units connect/disconnect the trip unit with the voltage connections in the circuit breaker. Before conducting any high-voltage tests on circuit breakers with Micrologic P and H trip units, remove the rating plug as shown

NOTE: Only Micrologic P and H trip units have phase voltage connections into the trip unit. For other types of trip units, it is not necessary to remove the rating plug prior to dielectric testing.

1. Open switch cover (Figure 15, A).
2. Unscrew rating plug mounting screw (B).
3. Remove rating plug (C).

Figure 15 – Removing Rating Plug

NOTICE

HAZARD OF EQUIPMENT DAMAGE

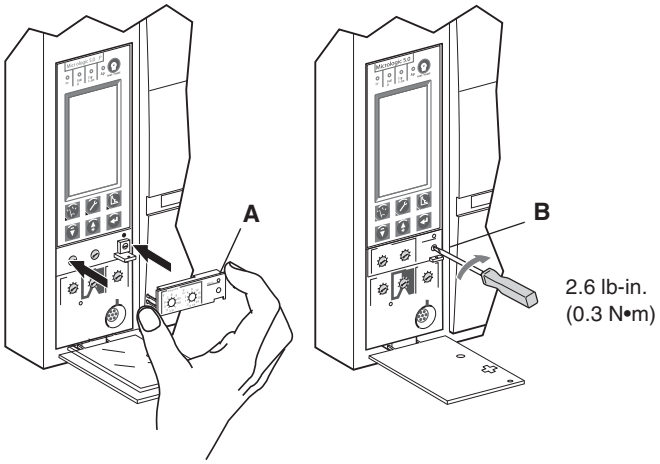
Do not apply test voltage to control circuits or accessory terminals; damage to electronic and/or low-voltage components can result.

Failure to follow these instructions can result in equipment damage.

Insulation Resistance Test

Severe environmental conditions can reduce the dielectric strength of molded case circuit breakers. Check insulation resistance during electrical system testing.

To check the insulation resistance, perform the following steps:



1. De-energize and isolate the circuit breaker:
2. Clean the circuit breaker as described earlier.
3. Using a megohmmeter with a capacity of 500–1000 Vdc, apply voltage from:
   a. Each phase-to-ground with the circuit breaker on (circuit breaker contacts closed).
   b. Phase-to-phase with the circuit breaker on (circuit breaker contacts closed).
   c. Between each line and load terminal with the circuit breaker off (circuit breaker contacts open).
4. Record resistance values. Resistance values of less than one megohm (1,000,000 ohm) should be investigated.

After testing is complete, replace rating plug if previously removed:

1. Replace rating plug (Figure 16, A).
2. Tighten rating plug mounting screw (B).

NOTE: If the rating plug is not installed, the circuit breaker will default to a long-time pickup setting of 0.4 x the sensor (I_n) and some of the advanced functions will not be operable.

Figure 16 – Replacing Rating Plug

Micrologic Trip Unit Checks

Circuit breakers with Micrologic trip units can have their trip unit operation tested with secondary injection testing using the one of the available test kits. (See page 58 for test kits.)

Secondary injection testing does not test the current transformers and connections. Primary injection testing can be used to ensure that all trip system connections have been correctly made.

If the circuit breaker is tested by the primary injection method, the Powerlogic™ system can remain connected to the circuit breaker during testing without affecting the results.

NOTE: Testing a circuit breaker connected to a Powerlogic system causes the Powerlogic system to react as if the circuit breaker were experiencing the actual faults.

Procedure to Defeat Zone-Selective Interlocking

Zone-selective interlocking is a method of communication between electronic-trip overcurrent protective devices. Zone-selective interlocking allows interlocked devices at different levels to work together as a system in which a short circuit or ground fault is isolated and cleared with minimum time delay. The purpose of defeating zone-selective interlocking is to verify the characteristics of the specific circuit breaker short-time and ground-fault trip delay functions. For test purposes, zone-selective interlocking can be inhibited on Masterpact circuit breakers equipped with Micrologic trip units by using the Hand-Held or Full-Function Test Kit.

Secondary Injection Testing

Field installation of a trip unit requires secondary injection testing with a Full-Function Test Kit. This will ensure that the newly-installed trip unit is functioning properly. The test will require opening and closing the circuit breaker. Follow the procedures outlined in the instruction bulletins shipped with the circuit breaker and the Full-Function Test Kit.

1. Make sure the circuit breaker is isolated from all upstream and downstream devices.
2. Perform secondary injection testing as outlined in the instruction bulletin shipped with the full-function test kit. Verify that all applicable trip unit functions are operating properly.
3. Repeat step 2 with the circuit breaker in the open position.

   NOTE: The test kit states that the circuit breaker should be closed when performing the test. Do not close the circuit breaker for this step.
4. If any test fails, do not put the circuit breaker into service and contact the local sales office for factory authorization service.

ENGLISH

Primary Injection Testing

Primary injection testing can be used to ensure that all trip system connections have been correctly made.

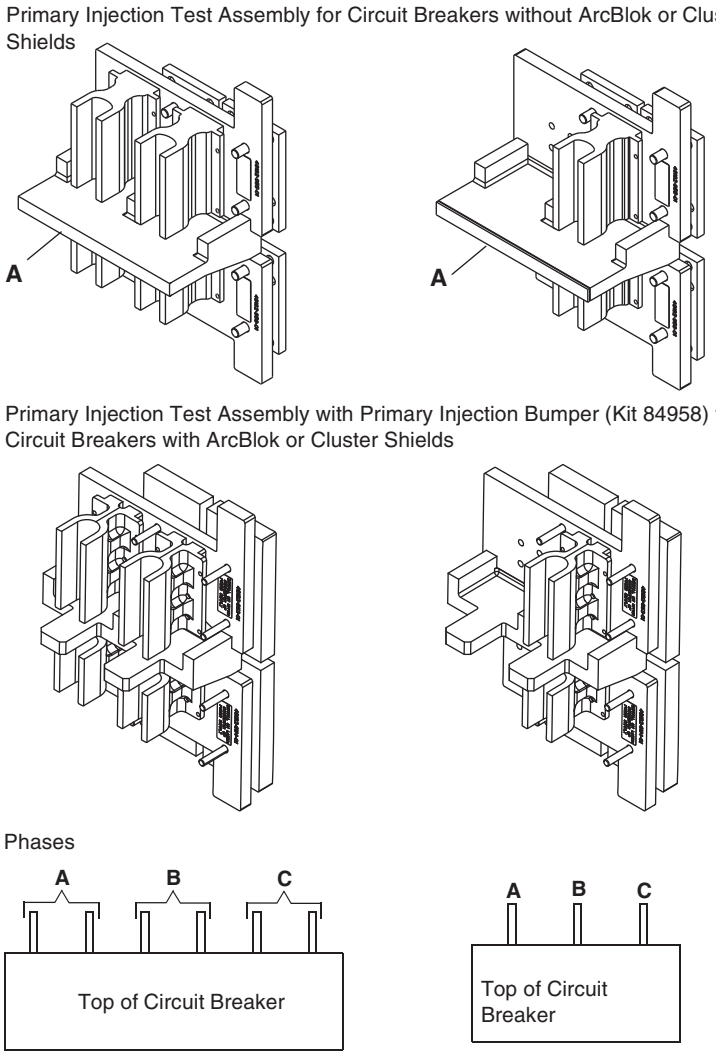
NOTE: Secondary injection testing continues to be the Schneider Electric preferred method for testing circuit breakers. Improper primary injection testing can cause damage to the circuit breakers. Failure to conduct primary injection testing in the proper manner could result in circuit breakers passing testing, while ultimately damaging the integrity of the circuit breaker long term.

NOTICE

HAZARD OF EQUIPMENT DAMAGE

- Circuit breakers are heavy and can be damaged with improper handling. Use care when handling and transporting circuit breakers to test equipment.
- Make connection to the circuit breaker carefully using rated cable and appropriate connection methods. Do not use clamps or other methods that can score or otherwise damage the finish of the connectors.
- When connecting a drawout-type circuit breaker, use approved primary injection test kit. Adjust circuit breaker position so circuit breaker clusters align with the primary injection test kit.

Failure to follow these instructions can result in equipment damage.



1. If performing primary injection testing on drawout circuit breakers, connect circuit breaker to power supply using primary injection test kits.

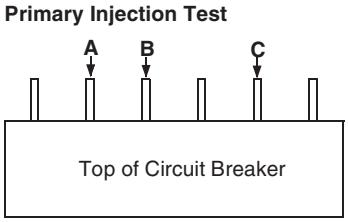
Figure 17 – Masterpact NW Primary Injection Test Assembly

a. Install primary injection test kit following instructions shipped with the test kit.

b. Adjust height of the circuit breaker so the stop (A, above) between the top and bottom plates of the test kit is between the top and bottom connectors of the circuit breaker when it is in the connected positions.

c. Align the circuit breaker so that the clusters on the circuit breaker phase being tested line up with the connectors with the primary injection test kit.

d. Use grease kit, catalog number S48899, to lubricate connectors. Do not install anything in the cluster jaw except approved test kit.



NOTE: Remove any existing grease from cluster assembly before applying new grease to clusters.

2. If performing primary injection testing on fixed circuit breakers, connect circuit breaker to power supply using rated cable and appropriate connection method.

NOTE: Wide-construction circuit breakers only—When primary injection testing a circuit breaker with six bus connectors, current is injected into phases as shown in Figure 18. Do not inject current into outside busses.

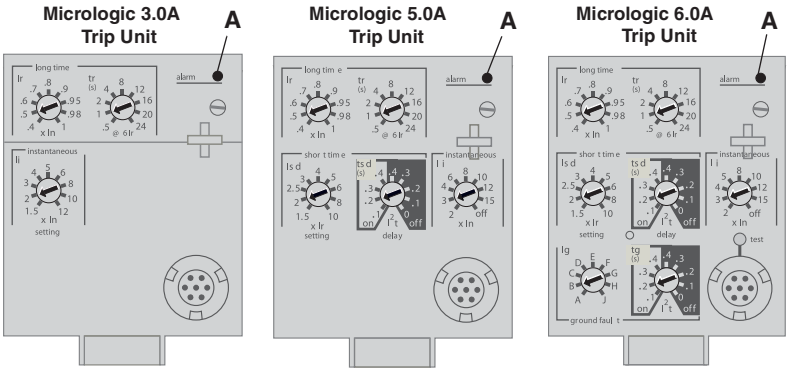
Figure 18 – Wide-Construction Circuit Breakers

3. Record each of the original trip unit switch settings. (Settings must be reset after testing is complete.)
4. Set the long-time pickup (I_r) switch (A) to the minimum setting.

Figure 19 – Record Switch Settings

a. For ground-fault and/or zone-selective interlocked trip units, use the hand-held or full-function test kit to inhibit ground-fault and zone-selective interlocking functions.

b. If an auxiliary power supply is being used for the Micrologic trip unit, disconnect the auxiliary power supply.



c. Find the primary injection current needed by multiplying the long-time pickup current (long-time pickup setting I_r x sensor plug I_n) x 125% (i.e. I_r x I_n x 1.25).

d. Inject primary current into A-phase and monitor the overload indicator light. Verify that the overload indicator light (A) lights between 105% and 120% of the I_r x I_n value.

e. Repeat for all phases and neutral (if applicable).

f. If overload indicator light does not light correctly, check all trip unit connections and test setup. If unit still fails primary injection testing, contact the local sales office.

Circuit Breakers with Integral Ground Fault Protection

Micrologic electronic-trip circuit breakers with the integral ground-fault protection function require special attention when testing overload and short-circuit functions. The single-pole primary injection tests for the inverse-time overcurrent, short-time and instantaneous functions will cause ground-fault trips due to the return current path not going through the circuit breaker. To overcome this difficulty, use the Hand-Held or Full-Function Test Kit to defeat the ground-fault function on Masterpact or PowerPact™ circuit breakers equipped with Micrologic trip units.

NOTE: When the hand-held or full-function test kits are used to inhibit ground-fault, the test kit puts the trip unit in "TEST MODE". While the trip unit is in this mode, the logs, alarms, and advanced protections are turned off so that a test trip is not recorded as an actual event. See the test kit instructions for further information.

Ground-Fault Protection and Indication Only Tests for Radial Systems

Ground-Fault Trip Test

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E, CSA Z462, or NOM-029-STPS.
- This equipment must be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

The ground-fault function of a Micrologic electronic-trip circuit breaker provides ground-fault protection for equipment with adjustable pickup and delay values. the ground-fault delay feature determines how long the circuit breaker waits before initiating a trip signal during a ground fault. Performance of the ground-fault functions of the circuit breaker can be tested using a high-current, low-voltage ac power supply.

Test Procedure

1. Completely de-energize and remove the circuit breaker from service.
2. Before testing, record pickup and delay setting for all functions. Reset the trip unit to these same settings after the test procedure is completed.
3. If testing a circuit breaker that is equipped with zone-selective interlocking, follow the procedure to defeat zone-selective interlocking on page 47. If you are using a secondary injection test kit for these tests, carefully read and follow the test kit instructions about zone-selective interlocking.

   NOTE: Failure to defeat zone-selective interlocking will result in trip time inaccuracy.

4. Use these settings for the test:

   Long-time Pickup/Ampere Rating = Max.

   Long-time/Overload Delay = Max

   Short-time/Short-circuit Delay = Max. (I^2t IN or ON)

   Instantaneous = Max.

   Ground-fault Pickup = Min.

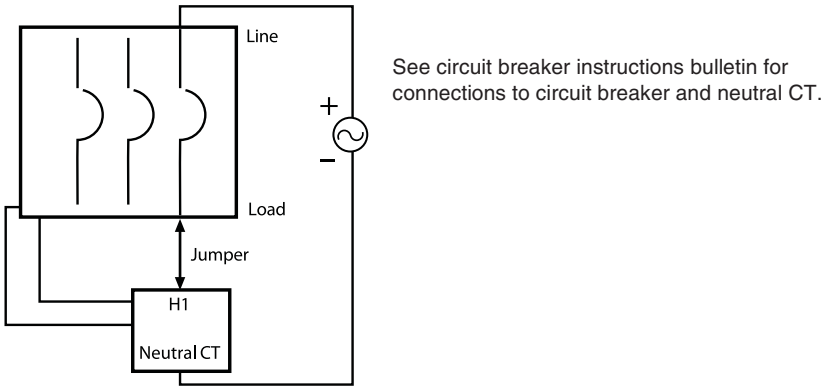
   Ground-fault Delay = 0.2

5. Follow the hookup procedure appropriate to the test application.

   For circuit breakers without a neutral current transformer, go to step 8.

   For circuit breakers with the integral ground-fault function in a three-phase, four-wire system, an externally-mounted neutral current transformer (CT) must be used. The neutral CT is connected to the circuit breaker by a shielded cable (14 AWG [2.1 mm2] wire is recommended).

   NOTE: When testing, disconnect or turn off 24 Vdc control power to F1 and F2, if equipped and disconnect the Hand-Held or Full-Function Test Kit from the trip unit, if connected.



6. Verify correct phasing of the neutral CT (three-phase, four-wire systems) by performing a No Trip Test as follows:

   a. Connect the circuit breaker and neutral CT as shown in Figure 21. The jumper must go from the load connection on the circuit breaker to the H1 connection on the neutral CT (or the side of the neutral CT that has the red dot). Connect the secondary of the neutral CT according to the circuit breaker instruction manual or the neutral CT instructions.

   b. Apply current above the ground-fault pickup level and maintain longer than the ground-fault delay.

   c. The circuit breaker must not trip. No trip indicates that both the phase CT and neutral CT are phased properly.

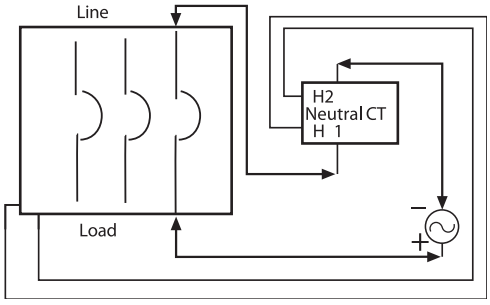


Figure 21 – Test Hookup Diagram for Neutral CT Phasing Test

 © 2012–2015 Schneider Electric All Rights Reserved

7. Verify the correct size of the neutral CT (three-phase, four-wire systems) by performing a Trip Test as follows:
   a. Connect the circuit breaker and neutral CT as shown in Figure 22. Connect the polarity (+) terminal of the high current injection unit to the load side of the circuit breaker. The jumper must go from the line connection on the circuit breaker to the H1 connection on the neutral CT (or the side of the neutral CT that has the red dot). Connect the non-polarity (-) terminal of the high current injection unit to H2 on the neutral CT (on the line side of the circuit breaker). Connect the secondary of the neutral CT according to the circuit breaker instruction manual or the neutral CT instructions.
   b. Apply current.
   c. The circuit breaker must trip at half the value of the ground-fault pickup. Tripping indicates that both the phase CT and neutral CT have the same turns ratio (same size).

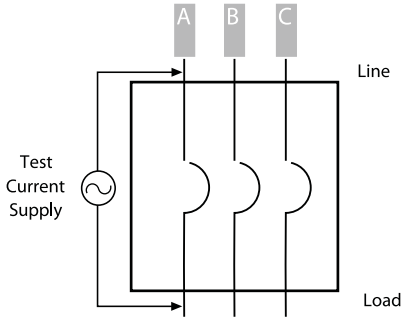

Figure 22 – Test Hookup Diagram for Neutral CT Size Test

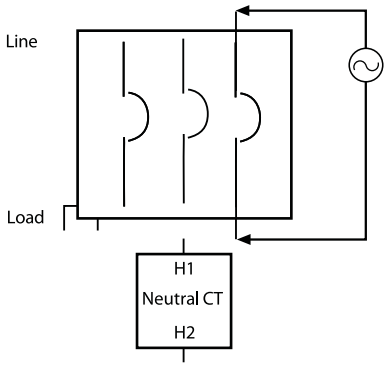
See circuit breaker instructions bulletin for connections to circuit breaker and neutral CT.



8. Test ground fault pickup and delay by performing a trip test as follows:
   a. Connect the circuit breaker as shown in Figure 23, (three-phase, three-wire systems) or Figure 24 (three-phase, four-wire systems).

Figure 23 – Test Hookup Diagram for Circuit Breaker Without Neutral CT

Figure 24 – Test Hookup Diagram for Ground-Fault Pickup and Delay Test

NOTE: The recommended method of testing ground-fault pickup and delay is the “pulse” method. This method will be the most accurate, but requires that the test equipment have a calibrated image-retaining oscilloscope or high-speed sampling rate digital ammeter. An accurate timer is needed to monitor delay time.

b. After the circuit is properly connected and closed, apply current in short pulses of 10-cycle duration. Starting at 70% of the expected trip value,

c. Reclose the circuit breaker and reduce the current level; pulse again to determine if the pickup level found was overshot.

d. Repeat steps b and c to further isolate the pickup point.

e. To determine delay time, test each pole of the circuit breaker individually at 150% of the ground-fault pickup setting. Monitor the time from this pickup point until the circuit breaker trips to obtain the delay time.

f. Record pickup and delay values and compare the results to the trip curve.

The ground-fault test can also be done using secondary injection testing using the Full-Function Test Kit. Secondary injection testing does not test the current transformers and connections.

Contact Resistance Test

Circuit breaker pole resistance tests are not reliable indicators of circuit breaker performance because the resistance values are influenced by a number of transient factors including contact surface oxidation, foreign material between the contacts, and testing methods. NEMA AB 4 paragraph 6.4.1 states: “The millivolt drop of a circuit breaker pole can vary significantly due to inherent variability in the extreme low resistance of the electrical contacts and connectors. Such variations do not necessarily predict unacceptable performance and shall not be used as the sole criteria for determination of acceptability.”

High pole resistance may also be caused by eroded contacts, low contact force, and loose termination. The only one of these factors likely to be present on a new circuit breaker is a loose termination, since the contacts are new and there has been no opportunity for contact pressure to have drifted from the factory setting. A loose termination can be corrected in the field.

If a contact resistance test is done, it is important to do it after the contacts have been conditioned by instantaneous primary injection testing to ensure the contacts are clear of resistive films, oxidation and foreign material. If the circuit breaker has been in service with no performance issues, (overheating or nuisance tripping), contact resistance measurements are redundant and of little value.

Square D™ recommends that a Digital Low Resistance Ohmmeter (DLRO) be used, using a 10 A dc test current for circuit breaker ratings below 100 A, and using 100 A dc for circuit breakers rated 100 A and above. the median (middle) value of three readings (toggling the circuit breaker between each reading) should be recorded for each pole tested. If this value is equal to or less than the value listed in Table 26, the pole is acceptable. If the reading is higher, the cause should be investigated and corrected if possible. Contact your local field office for more information.

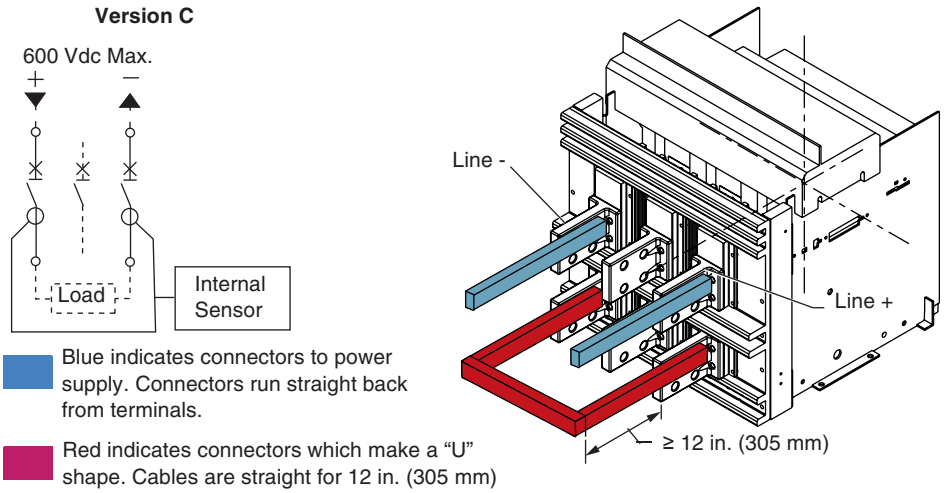
Circuit Breakers with Direct Current Protection

The Masterpact NW DC circuit breakers are designed, manufactured and calibrated for use on ungrounded, uninterruptable power supplies (UPS). The maximum nominal (loaded) voltage is 500 Vdc and the maximum floating (unloaded) voltage is 600 Vdc.



These circuit breakers are UL Listed when applied with all poles connected in series as shown on the label of the circuit breaker. The series connection is customer provided and external to the circuit breakers.

The Masterpact NW DC circuit breakers are special circuit breakers for dc applications only and must be tested using dc current.

- Select the correct time-current trip curve. The trip curves show both the thermal and magnetic trip ranges of the circuit breakers.
- Use a dc power supply to test the circuit breakers as follows:
  - — Time constant ≤ 25 ms
  - — DC ripple constant ≤ 1% rms
- Remove the circuit breaker from the enclosure. If removing the circuit breaker is not practical, test the circuit breaker in the end-use equipment. If the test results fall outside of the trip curve tolerance, remove the circuit breaker from the enclosure and retest.
- Use correctly sized cable (per National Electrical Code® [NEC®] tables) with a minimum of four feet (1.22 m) of cable per connection.
- Connect a dc power supply to the circuit breaker with all poles connected in series as shown on the circuit breaker label (see Figure 25–27).
- Make sure connections to circuit breaker are properly torqued.
- Apply a dc test current to the circuit breaker of approximately 70% of the expected value to trip the circuit breaker. The tripping mechanism in the circuit breaker reacts to the magnetic fields created by the current flowing through the circuit breaker. If the circuit breaker does not trip, increase the test current on successive trials until it does trip. When the circuit breaker trips:
  a. Reset and close the circuit breaker.
  b. Reapply the dc test current to trip the circuit breaker again.
  c. Record the current and compare to the trip curve.

Remove Test Connections Upon Completing Testing:

- — Remove test connections from circuit breaker.
- — Inspect connections for damage caused by testing.
- — For drawout circuit breakers, inspect, lubricate, and reset clusters before installing circuit breaker, see page 31.
- — Reset the long-time pickup switch to original settings, as recorded above.
- — If an auxiliary power supply is being used for the Micrologic trip unit, reconnect the auxiliary power supply.

Test Kit Information

Full-Function Test Kit

The Full-Function Test Kit is a microprocessor-based system used to test Compact™ NSJ, Masterpact and PowerPact circuit breakers with Micrologic electronic-trip units. The Full-Function Test Kit is a secondary injection tester and does not test the current transformers and connections.

The Full-Function Test Kit is designed to be used as a stand-alone test unit or in conjunction with a personal computer. The Full-Function Test Kit alone performs the following tests:

- Protection function verification (LSIG)
- Compliance with trip curve
- Electrical and mechanical tests of trip system
- Zone-selective interlocking tests
- Inhibition of ground-fault protection for use during primary injection testing
- Inhibition of thermal imaging for use during primary injection testing
- Supply control power to the trip unit to energize displays

 © 2012–2015 Schneider Electric All Rights Reserved

Hand-Held Test Kit

The Hand-Held Test Kit is a small battery-powered unit. It is designed to provide convenient secondary injection tests on Compact NSJ, Masterpact and PowerPact circuit breakers with Micrologic electronic-trip units. The Hand-Held Test Kit is powered by five 9 V batteries and can be used to do the following:

- Verify trip unit operation by tripping the circuit breaker with a secondary injection signal
- Supply control power to the trip unit to energize displays
- Inhibit thermal imaging for primary injection testing
- Inhibit ground-fault for primary injection testing
- Zone-selective interlocking tests[1]

Anti-Pumping Feature

All Masterpact NT and NW circuit breakers are designed with an anti-pumping feature which always gives priority to an opening order over a closing order. Specifically, if opening and closing orders occur simultaneously, the charged mechanism discharges without any movement of the main contacts keeping the circuit breaker in the open (OFF) position. In the event that opening and closing orders are simultaneously maintained, the standard mechanism provides an anti-pumping function which continues to keep the main contacts in the open position. In addition, after fault tripping or opening the circuit breaker intentionally (using the manual or electrical controls and with the closing coil continuously energized) the circuit breaker cannot be closed until the power supply to the closing coil is discontinued and then reactivated.

Anti-Pump Check for Electrically Operated Circuit Breakers

If desired, use the following procedure to assure that the anti-pump feature works properly.

1. Open the circuit breaker.
2. Energize the control power for the spring charging motor, shunt trip and shunt close.
3. Spring charging motor will charge the springs whenever they are discharged (during circuit breaker closing).
4. Make sure all interlocks, etc. are disengaged and the circuit breaker is ready to close. Press and hold the Close pushbutton (use the remote close button connected to the shunt close if desired). Verify the circuit breaker closed. Wait for the spring charging motor to complete the spring charge.
5. While continuing to hold the Close button, press the Open button. Make sure the circuit breaker opens and does not reclose.
6. Release the Close button.
7. If circuit breaker does not attempt to reclose, the anti-pump feature is working correctly.
8. Press the Open button and then the Close button.
9. Press and release the Close pushbutton (use the remote close button connected to the shunt close if desired). Verify the circuit breaker closed. Wait for the spring charging motor to complete the spring charge.

[1] Only provides power to trip unit to indicate a ZSI signal was received. Will not initiate the command to send a ZSI restraint signal.

 © 2012–2015 Schneider Electric All Rights Reserved

10. Press the Open button. Make sure the circuit breaker opens.
11. Repeat steps 8, 9 and 10 to make sure the circuit breaker opens and closes correctly.

Anti-Pump Check for Manually Operated Circuit Breakers

1. Open the circuit breaker.
2. Operate the spring charging handle to charge the closing springs.
3. Make sure all interlocks, etc. are disengaged and the circuit breaker is ready to close. Press and hold the Close pushbutton. Verify the circuit breaker closed.
4. Operate the spring charging handle to charge the closing springs.
5. While continuing to hold the Close button, press the Open button. Make sure the circuit breaker opens and does not reclose.
6. Release Close button.
7. If circuit breaker does not attempt to reclose, the anti-pump feature is working correctly.
8. Press the Open button and then the Close button.

Additional Information

For more information concerning Schneider Electric and Square D brand circuit breakers, refer to the appropriate instruction manual. These manuals contain installation instructions, mounting information, safety features, wiring diagrams, and troubleshooting charts for specific circuit breakers.

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

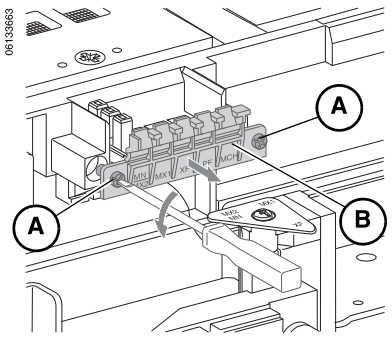
Failure to follow these instructions will result in death or serious injury.

PELIGRO DE DESCARGA ELÉCTRICA, EXPLOSIÓN O DESTELLO POR ARQUEO

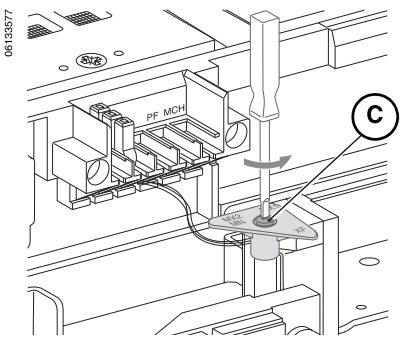
- Utilice equipo de protección personal (EPP) apropiado y siga las prácticas de seguridad eléctrica establecidas por su Compañía, consulte la norma 70E de NFPA.
- Solamente el personal eléctrico especializado deberá instalar y prestar servicio de mantenimiento a este equipo.
- Desenergice el equipo antes de realizar cualquier trabajo en él.
- Siempre utilice un dispositivo detector de tensión nominal adecuado para confirmar la desenergización del equipo.
- Vuelva a colocar todos los dispositivos, las puertas y los frentes antes de energizar el equipo.

El incumplimiento de estas instrucciones podrá causar la muerte o lesiones serias.

RISQUE D'ÉLECTROCUTION, D'EXPLOSION OU D'ÉCLAIR D'ARC



- Portez un équipement de protection personnelle (ÉPP) approprié et observez les méthodes de travail électrique sécuritaire. Voir NFPA 70E.
- Seul un personnel qualifié doit effectuer l'installation et l'entretien de ce appareil.
- Couper l'alimentation de l'appareil avant d'y travailler.
- Utilisez toujours un dispositif de détection de tension ayant une valeur nominale appropriée pour vous assurer que l'alimentation est coupée.
- Replacez tous les dispositifs, les portes et les couvercles avant de mettre l'appareil sous tension.



Si ces directives ne sont pas respectées, cela entraînera la mort ou des blessures graves.

1. Disconnect circuit breaker as directed in the circuit breaker instruction bulletin shipped with the circuit breaker.
2. Turn off or trip fixed circuit breaker by pressing push-to-trip button.
3. Remove accessory cover as directed in the circuit breaker instruction bulletin shipped with the circuit breaker.
4. Remove two screws (A) from center wiring cover and remove the wiring cover (B).
5. Loosen coil retainer screw (C) three turns

1. Desconecte el interruptor tal como se indica en el boletín de instrucciones correspondiente incluido.
2. Desconecte o dispare el interruptor fijo presionando el botón de disparo.
3. Retire la cubierta de accesorios tal como se indica en el boletín de instrucciones correspondiente incluido.
4. Retire los dos tornillos (A) de la cubierta central del cableado y retire la cubierta (B).
5. Dé tres vueltas al tornillo del sujetador de la bobina (C) para aflojarlo

1. Débrancher le disjoncteur selon les directives d'utilisation du disjoncteur qui l'accompagnent.
2. Déclencher ou mettre le disjoncteur fixe hors tension en appuyant sur le bouton pousser-pour-déclencher.
3. Enlever le couvercle des accessoires selon les directives d'utilisation accompagnent le disjoncteur
4. Retirer les deux vis (A) du couvercle de câblage de centre et enlever le couvercle (B)
5. Desserrer la vis du dispositif de retenue de bobine (C) de trois tours.

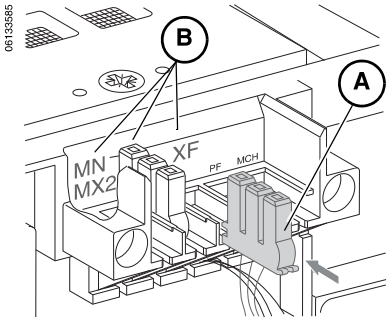
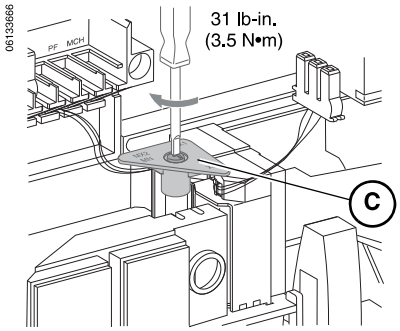
6. Lift coil retainer and install undervoltage trip MN or shunt trip MX2 (A), shunt trip MX1 (B) and/or shunt close XF (C) as shown below, placing tabs in designated holes (D) and aligning nubs on coil(s) with indentations on coil retainer (E)

6. Levante el sujetador de la bobina e instale el disparo por baja tensión MN o disparo en derivación MX2 (A), disparo en derivación MX1 (B) y/o cierre en derivación XF (C) como se muestra. Coloque las lengüetas en los agujeros designados (D) y alinee las muescas en la(s) bobina(s) con las hendiduras en el sujetador de la bobina (E).



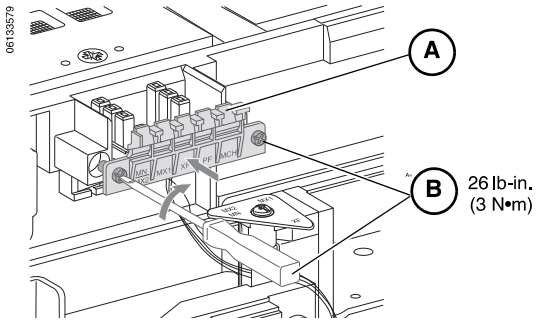
6. Soulever le dispositif de retenue de bobine et installer le déclencheur sur baisse de tension MN ou le déclencheur shunt MX2 (A), le déclencheur shunt MX1 (B) ou le fermeture en shunt XF (C), comme indiqué. Insérer les languettes dans les trous désignés (D) et aligner les ergots sur les bobines avec les bosses du dispositif de retenue de bobine (E).



7. Install coil wiring (A) into corresponding auxiliary control connection slots (B).
8. Lower coil retainer (C) and secure with screw

7. nstale el cableado de la bobina (A) en la(s) ranura(s) correspondiente(s) (B) de la conexión al control auxiliar.
8. Vuelva a colocar el sujetador de la bobina (C) y sujételo con el tornillo.

7. Installer le câblage de la bobine (A) dans la fente correspondante (B) de la connexion de commande auxiliare.
8. Remettre en place le dispositif de retenue de bobine (C) et le fixer à l'aide de la vis.



9. Reinstall wiring cover (A) using two previously removed screws (B)

9. Vuelva a instalar la cubierta del cableado (A) utilizando los dos tornillos retirados anteriormente (B).

9. Réinstaller le couvercle de câblage (A) à l'aide des deux vis (B) précédemment retirées.

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to potential personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates an imminently hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a potentially hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a potentially hazardous situation which, if not avoided, **can result in** minor or moderate injury.

CAUTION

CAUTION, used without the safety alert symbol, indicates a potentially hazardous situation which, if not avoided, **can result in** property damage.

Provides additional information to clarify or simplify a procedure.

PLEASE NOTE

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

SECTION 1—INTRODUCTION

Description

This bulletin contains inspection and testing instructions for modified differential ground fault protection systems manufactured by Schneider Electric.
The modified differential ground fault protection system used in Schneider Electric multiple-source switchboard and switchgear line-ups will use one of two types of ground fault current sensing techniques.

The first type is zero sequence sensing, which uses a single sensor to surround all three phase conductors and the neutral conductor. The second type is residual sensing, where each phase and the neutral conductor are surrounded by its own sensor. In normal conditions, the vector sum of the phase currents with the neutral current should equal zero. In a ground fault condition, the vector sum yields a current that is used in a protective relaying scheme to automatically open main or tie circuit breakers (or switches) as required.

NOTE: All diagrams are shown as residual sensing.

Testing

Paragraph 230-95(c) of the National Electrical Code® (NEC)® requires that all ground fault protection systems be performance tested when first installed. Schneider Electric recommends testing be done:

- When the equipment is installed at its permanent location.
- As a part of normal maintenance.
- If the distribution system is altered in any way.

Field testing determines that the ground fault protection system is operational. Consider the following information when using this instruction bulletin:

- The diagrams in this bulletin are provided to illustrate high current injection test connections, but are not intended to depict the ground fault protection system in its entirety as installed in the field. Review all instruction manuals and wiring diagrams provided with the equipment for actual system configuration. Verify that all sensors are installed and wired with correct polarity per the wiring diagrams.
- This field test procedure is not a check of the calibration of any sensing relay.
- Record results within the ground fault test logs (Tables 1–3 on pages 31–33). If test results are not acceptable, recheck the connections and retest. If results are still unacceptable, contact Square D Services at 1-888-Square D (1-888-778-2733).

Tools Required

The following tools are required to inspect and test the modified differential ground fault protection system:

- A high current injection test unit capable of injecting 1000 A. Test jumpers are typically copper welding cables. Use cables and connections that give low impedance.
- Hand-held test kit by Schneider Electric for Micrologic®
  Type A, H and P trip units.

Systems Covered

This test procedure is restricted to the following types of systems:

- Main-Main, Grounded Wye Configuration
- Main-Tie-Main, Grounded Wye, Non-Relayed Tie Configuration
- Main-Tie-Main, Grounded Wye, Relayed Tie Configuration

NOTE: A relayed system has ground fault protection on the Tie device. A non-relayed system has no ground fault protection on the Tie device.

NOTE: Systems with configurations beyond what are covered in this document can be tested with similar methods as those shown. All possible configurations of open and closed circuit breakers must be tested for both TRIP and NO TRIP functionality. TRIP tests always have the TEST JUMPER connected phase-to-ground. NO TRIP tests always have the TEST JUMPER connected phase-to-neutral (if neutral is not present, connect TEST JUMPER phase-to-phase).

SECTION 2—SAFETY PRECAUTIONS

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This test procedure must be performed only by qualified electrical personnel.
- Turn off all power before working on or inside the equipment. Assume that circuits are live until they have been completely de-energized, tested, and tagged. Pay particular attention to the design of the power system. Consider all sources of power, including the possibility of backfeeding.
- Always use a properly rated voltage sensing device to confirm that all power is off.
- Always practice lock-out/tag-out procedures according to the OSHA requirements.
- Conduct electrical testing to confirm that no short-circuits were created during installation, maintenance, or testing.
- Carefully inspect your work area and remove any tools and objects left inside the equipment.
- Replace all devices, doors, and covers before turning on power to this equipment.
- All instructions in this manual are written with the assumption that the customer has taken these measures before performing maintenance or testing.

Failure to follow these instructions will result in death or serious injury.

SECTION 3—MAIN-MAIN, GROUNDED WYE CONFIGURATION

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- This equipment must be installed and serviced only by qualified electrical personnel.
- Turn off all power supplying the equipment before working on or inside the equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors, and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

1. Turn off all power supplying this equipment before working on or inside equipment. Use a properly rated voltage sensing device to confirm power is off.
2. Verify that all ground bus bar splices are solidly connected. For each main, verify that the ground bonding connection is made ahead of the neutral disconnect link and on the line side of any ground fault sensor. See Figure 1.
3. For each main, verify that a neutral connection exists from the supply transformer to the equipment.
4. For residual sensing systems, verify that all phase and neutral sensors are connected with correct polarity on both primary and secondary. Refer to the drawings supplied with the equipment.
5. For zero sequence sensing systems, verify that all phase conductors and the neutral pass through the sensor in the same direction, and that grounding conductors do not pass through the sensor. Also, verify that the sensor is connected with the correct polarity on both primary and secondary. Refer to the drawings supplied with the equipment.
6. Remove each main's neutral disconnect link to isolate wiring system neutrals from both supply and ground.
7. Measure the system neutral-to-ground insulation resistance to ensure that no ground connections exist on the load side of the ground fault protection system. The resistance should be at least 1.0 megohm. Remove all connections that exist from neutral-to-ground found during the test. Do not reconnect these grounds after the test is completed.
8. Replace each main's neutral disconnect link.
9. Record all pick-up and time delay settings for each circuit breaker and/or ground fault relay under test in Table 4 on page 34. After testing, return all settings to original values.
10. Adjust the ground fault pick-up setting on each circuit breaker and/or ground fault relay to its lowest current setting.
11. Adjust the ground fault time delay setting on each circuit breaker and/or ground fault relay under test to 0.1 seconds (I2T OUT or OFF).
12. Adjust the long-time, short-time, and instantaneous pick-up and time delay settings on each circuit breaker under test to their highest settings.
13. For each circuit breaker equipped with the Micrologic® Type A, H, or P trip unit, connect a hand-held test unit, and activate the thermal-imaging inhibit function according to the test unit instructions. This step is necessary to inhibit trip history and contact wear counter functions. After testing, de-activate the thermal-imaging inhibit function according to the

test unit instructions. Refer to bulletin 48049-184-XX for additional information.

14. Disconnect the ground fault protection control power source, if internally derived, and provide control power from an external source. Refer to wiring diagrams supplied for specific connections. After testing, disconnect external control power and re-connect internal control power circuit.

Test No. 1

1. Close MAIN 1 circuit breaker (or switch), and open MAIN 2 circuit breaker (or switch).
2. On the line side of MAIN 1 circuit breaker (or switch), connect the high current injection unit between Phase A and the neutral (N). See Figure 1.
3. On the load bus, connect a high current jumper between Phase A and the neutral (N). See Figure 1.
4. Inject 1000 A into Phase A. MAIN 1 circuit breaker (or switch) should not trip on ground fault. Record the actual results for Test No. 1 in Table 1 on page 31.
5. Repeat Test No. 1 for Phases B and C (not required for zero sequence systems). Record the actual results for this test in Table 1.

Test No. 2

1. Close MAIN 1 circuit breaker (or switch), and open MAIN 2 circuit breaker (or switch).
2. On the line side of MAIN 1 circuit breaker (or switch), connect the high current injection unit between Phase A and the neutral (N). See Figure 2.
3. On the load bus, connect a high current jumper between Phase A and the ground. See Figure 2.
4. Inject 1000 A into Phase A. MAIN 1 circuit breaker (or switch) should trip on ground fault. Record the actual results for Test No. 2 in Table 1 on page 31.
5. Repeat Test No. 2 for Phases B and C (not required for zero sequence systems). Record the actual results for this test in Table 1.

Test No. 3

1. Close MAIN 2 circuit breaker (or switch), and open MAIN 1 circuit breaker (or switch).
2. On the line side of MAIN 2 circuit breaker (or switch), connect the high current injection unit between Phase A and the neutral (N). See Figure 3.
3. On the load bus, connect a high current jumper between Phase A and the neutral (N). See Figure 3.
4. Inject 1000 A into Phase A. MAIN 2 circuit breaker (or switch) should not trip on ground fault. Record the actual results for Test No. 3 in Table 1 on page 31.
5. Repeat Test No. 3 for Phases B and C (not required for zero sequence systems). Record the actual results for this test in Table 1.

Test No. 4

1. Close MAIN 2 circuit breaker (or switch), and open MAIN 1 circuit breaker (or switch).
2. On the line side of MAIN 2 circuit breaker (or switch), connect the high current injection unit between Phase A and the neutral (N). See Figure 4.
3. On the load bus, connect a high current jumper between Phase A and the ground. See Figure 4.
4. Inject 1000 A into Phase A. MAIN 2 circuit breaker (or switch) should trip on ground fault. Record the actual results for Test No. 4 in Table 1 on page 31.
5. Repeat Test No. 4 for Phases B and C (not required for zero sequence systems). Record the actual results for this test in Table 1.
6. After testing, return all settings to the original values previously recorded.

Test No. 6

1. Close MAIN 1 circuit breaker (or switch). Open TIE circuit breaker (or switch), and close MAIN 2 circuit breaker (or switch).
2. On the line side of MAIN 2 circuit breaker (or switch), connect the high current injection unit between Phase A and the neutral (N). See Figure 18.
3. On the load bus, connect a high current jumper between Phase A and the ground. See Figure 18.
4. Inject 1000 A into Phase A. MAIN 2 circuit breaker (or switch) should trip on ground fault. Record the actual results for Test No. 6 in Table 3 on page 33.
5. Repeat Test No. 6 for Phases B and C (not required for zero sequence systems). Record the actual results for this test in Table 3.

Test No. 7

1. Open MAIN 1 circuit breaker (or switch). Close TIE circuit breaker (or switch), and close MAIN 2 circuit breaker (or switch).
2. On the line side of MAIN 2 circuit breaker (or switch), connect the high current injection unit between Phase A and the neutral (N). See Figure 19.
3. On the load bus, connect a high current jumper between Phase A and the neutral (N). See Figure 19.
4. Inject 1000 A into Phase A. Neither MAIN 2 circuit breaker (or switch) nor TIE circuit breaker (or switch) should trip on ground fault. Record the actual results for Test No. 7 in Table 3 on page 33.
5. Repeat Test No. 7 for Phases B and C (not required for zero sequence systems). Record the actual results for this test in Table 3.

Schneider Electric™

Hazard Categories and Special Symbols

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

ANSI 

This is the safety alert symbol. It is used to alert you to potential personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

IEC 

⚠ DANGER

DANGER indicates a hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a hazardous situation which, if not avoided, **can result in** minor or moderate injury.

NOTICE

NOTICE is used to address practices not related to physical injury. The safety alert symbol is not used with this signal word.

NOTE: Provides additional information to clarify or simplify a procedure.

Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

FCC Notice

This equipment has been tested and found to comply with the limits for a Class A digital device, pursuant to part 15 of the FCC Rules. These limits are designed to provide reasonable protection against harmful interference when the equipment is operated in a commercial environment. This equipment generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with the instruction manual, may cause harmful interference to radio communications. Operation of this equipment in a residential area is likely to cause harmful interference in which case the user will be required to correct the interference at his own expense. This Class A digital apparatus complies with Canadian ICES-003.

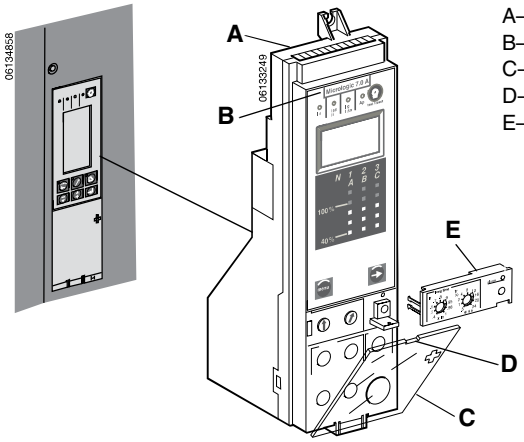
Section 1— General Information

Introduction



Micrologic™ trip units (A) provide adjustable tripping functions on electronic trip circuit breakers. The product name (B) specifies the level of protection provided by the trip unit.

Micrologic 3.0A

- Type of protection
  - 2—Basic IEC protection (LS0)
  - 3—Basic UL protection (LI)
  - 5—Selective protection (LSI)
  - 6—Selective protection plus ground fault protection for equipment (LSIG)
- Trip unit series
  - 0—Indicates the first version
- Type of measurement
  - None—Provides protection only
  - A—Provides protection plus ammeter measurements

Micrologic trip units are field replaceable to allow for upgrading of the trip unit in the field. For complete information on available circuit breaker models, frame sizes, interrupting ratings, sensor plugs, rating plugs and trip units, see the product catalog.

Communications

Micrologic trip units can communicate with other devices if the optional Circuit Breaker Communication Module (BCM) is installed. For information on the register lists and other communication devices refer to bulletin 0613IB1313: *Modbus Communications System*.

Trip Unit Settings

On the face of the trip unit are adjustable switches to allow changing of trip characteristics. Trip units are shipped with the long-time pickup switch set at 1.0 and all other trip unit adjustments set at their lowest settings.

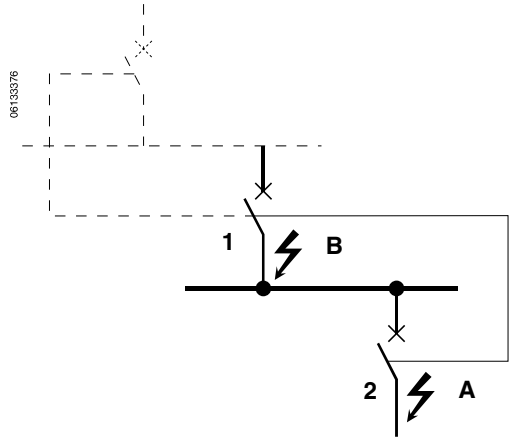
Zone-Selective Interlocking

Short-time and ground-fault protection can be interlocked to provide zone-selective interlocking.

NOTE: Use I^2t off with ZSI for proper coordination. Using I^2t on with ZSI is not recommended as the delay in the upstream device receiving a restraint signal could result in the trip unit tripping in a time shorter than the published trip curve.

NOTE: Setting short-time delay (tsd) or ground-fault delay (tg) to the 0 setting will eliminate selectivity for that circuit breaker.

Control wiring links several trip units in the distribution network and in the event of a fault, a trip unit will obey the set delay time only if receiving a signal from a downstream trip unit.



If the trip unit does not receive a signal, tripping will be instantaneous (with no intentional delay).

- The fault is cleared instantaneously by the nearest upstream circuit breaker.
- Thermal stresses (I^2t) in the network are minimized without any effect on the correct time delay coordination of the installation.

Figure 6 shows circuit breakers 1 and 2 zone-selective interlocked.

- A fault at A is seen by circuit breakers 1 and 2. Circuit breaker 2 trips instantaneously and also informs circuit breaker 1 to obey set delay times. Thus, circuit breaker 2 trips and clears the fault. Circuit breaker 1 does not trip.
- A fault at B is seen by circuit breaker 1. Circuit breaker 1 trips instantaneously since it did not receive a signal from the downstream circuit breaker 2. Circuit breaker 1 trips and clears the fault. Circuit breaker 2 does not trip.

Long-Time Protection

Long-time protection protects equipment against overloads.

NOTE: Micrologic trip units are powered from the circuit to always provide fault protection. All other functions (display, metering, communications, etc.) require external power. See page 18 for more information.

- Long-time protection is standard on all trip units.
- The long-time pickup (Ir) (A) sets the maximum current level (based on sensor plug rating In) which the circuit breaker can continuously carry. If current exceeds this value, circuit breaker will trip after the preset time delay. The long-time pickup (Ir) is adjustable from 0.4–1.0 times the sensor plug rating (In).
- The long-time delay (tr) (B) sets the length of the time that the circuit breaker will carry an overcurrent (below the short-time or instantaneous pickup current level) before tripping. See Table 1 on page 12 for delay settings.
- Both long-time pickup and long-time delay are on the field-replaceable adjustable rating plug. To change settings to more precisely match the application, various rating plugs are available. For instructions on replacing the rating plug, see Section 5 —Adjustable Rating Plug Replacement.
- For Masterpact™ NT and NW circuit breakers, the In value can be changed by replacing the sensor plug below the trip unit. For further information, see the instructions packed with the sensor plug replacement kit.
- The overload indicator light (C) indicates that the Ir long-time pickup threshold has been exceeded.
- Long-time protection uses true RMS measurement.

Figure 7 – Long-Time Protection Switches

Table 1 – Micrologic Trip Unit Long-Time Delay Values

Setting[1]	**Long-Time Delay in Seconds[2]**								
tr at 1.5 x Ir	12.5	25	50	100	200	300	400	500	600
tr at 6 x Ir	0.5	1	2	4	8	12	16	20	24
tr at 7.2 x Ir	0.34[3]	0.69	1.38	2.7	5.5	8.3	11	13.8	16.6

[1]Ir = In x long-time pickup. In = sensor rating. Trip threshold between 1.05 and 1.20 Ir.
[2]Time-delay accuracy +0/-20%
[3]For Micrologic 5.0A and 6.0A trip units, when tsd is set to 0.4 on or 4.0 off, then tr = 0.5 instead of 0.34.

Thermal imaging provides continuous temperature rise status of the wiring, both before and after the device trips. This allows the circuit breaker to respond to a series of overload conditions which could cause conductor overheating, but would go undetected if the long-time circuit was cleared every time the load dropped below the pickup setting or after every tripping event.

NOTE: If checking trip times, wait a minimum of 15 minutes after circuit breaker trips before resetting to allow the thermal imaging to reset completely to zero or use a full-function test kit to defeat the thermal imaging.

Short-Time Protection

Short-time protection protects equipment against short circuits.

- Short-time protection is standard on 2.0A, 5.0A and 6.0A trip units. It is not available on 3.0A trip units.
- Short-time protection is based on the long-time pickup (Ir).
- The short-time pickup (Isd) (A) sets current level (below instantaneous trip level) at which circuit breaker will trip after the preset time delay.
- The short-time delay (tsd) (B) sets the length of time that the circuit breaker will carry an overcurrent above the short-time pickup current level before tripping. It is adjustable on the 5.0A and 6.0A trip unit and factory set to zero on the 2.0A trip unit.

Setting	Short-Time Delay				
I^2t off (Isd at 10 Ir) (seconds)	0	0.1	0.2	0.3	0.4
I^2t on (Isd at 10 Ir) (seconds)		0.1	0.2	0.3	0.4
tsd (min. trip) (milliseconds)	20	80	140	230	350
tsd (max. trip) (milliseconds)	80	140	200	320	500

- The I^2t on/I^2t off option provides improved selectivity with downstream protective devices:
  - — With I^2t off selected, fixed time delay is provided.
  - — With I^2t on selected, inverse time I^2t protection is provided up to 10 x Ir. Above 10 x Ir, fixed time delay is provided.
- Intermittent currents in the short-time tripping range which do not last sufficiently long to trigger a trip are accumulated and shorten the trip delay appropriately.
- Short-time protection can be zone-selective interlocked (ZSI) with upstream or downstream circuit breakers.
- Setting tsd to the 0 setting turns off zone-selective interlocking.
- Short-time protection uses true RMS measurement.
- Short-time pickup and delay can be adjusted to provide selectivity with upstream or downstream circuit breakers.

NOTE: Use I^2t off with ZSI for proper coordination. Using I^2t on with ZSI is not recommended as the delay in the upstream device receiving a restraint signal could result in the trip unit tripping in a time shorter than the published trip curve.

Instantaneous Protection

Instantaneous protection protects equipment against short circuits with no intentional time delay.

- Instantaneous protection (Ii) (A) is standard on the 3.0A, 5.0A and 6.0A trip units.
- Instantaneous protection on 2.0A trip units is achieved by using short-time protection (Isd) with the short-time delay factory set to 0 (zero).
- Instantaneous protection on the 3.0A, 5.0A and 6.0A trip units is based on the circuit breaker sensor rating (In).
- Instantaneous protection on the 2.0A trip unit is based on the long-time pickup setting (Ir).
- Circuit breaker open command is issued as soon as threshold current is exceeded.
- Instantaneous protection uses peak current measurement.
- When instantaneous protection switch is set to off, the instantaneous protection is disabled.

Ground-Fault Protection

Equipment ground-fault protection protects conductors against overheating and faults from ground-fault currents (≤ 1200 A).

- Equipment ground-fault protection is standard on 6.0A trip units.
- Ground-fault pickup (Ig) (A) sets ground current level where circuit breaker will trip after the preset time delay.
- Ground-fault delay (tg) (B) sets the length of time that the circuit breaker will carry a ground-fault current above the ground-fault pickup current level before tripping.
- Equipment ground-fault protection can be zone-selective interlocked (ZSI) with upstream or downstream circuit breakers.
- Setting the ground-fault delay (tg) to the 0 setting turns off zone-selective interlocking.
- Neutral protection and equipment ground-fault protection are independent and can operate concurrently.

NOTE: Use I^2t off with ZSI for proper coordination. Using I^2t on with ZSI is not recommended as the delay in the upstream device receiving a restraint signal could result in the trip unit tripping in a time shorter than the published trip curve.

Ammeter

The ammeter monitors and displays the circuit breaker currents. An alphanumeric screen (A) continuously displays the phase at the highest load. Navigation buttons (B) can be pressed to display the various monitored currents.

The process of checking the ammeter values can be stopped at any time. After several seconds, Micrologic trip units automatically return to displaying the phase at the highest load.

See the following section for addition information concerning the ammeter.

400–1200 A	20% of Sensor Rating
1600–6300 A	500 A

The A trip unit was designed to be used with or without an external 24 Vdc power supply.

The following will be powered and functional even if the trip unit is not externally powered:

- Fault protection for LSIG functions. The A trip unit is fully circuit powered for fault protection.
- LED trip indication (powered by an onboard battery). The battery's only function is to provide LED indication if all other power is off
- All display functions and trip unit features power-up with current flow on one phase greater than or equal to the values in Table 6.
- Ground-fault push-to-trip button works for testing ground fault with current flow on one phase greater than or equal to the values in Table 6.

 © 1999–2015 Schneider Electric All Rights Reserved

The ground-fault push-to-trip is also functional if a Hand-Held Test Kit or Full-Function Test Kit is powering the trip unit.

The following will be powered and functional with external power:

- All of the above functions which are functional without external power.
- Ammeter and bar graph displays are functional with or without current flowing through the circuit breaker. With current flow between 0 and 20% of sensor value, the ammeter may not be accurate.
- Trip settings and max. current readings can be accessed on the display be pressing the navigation buttons with or without current flowing through the circuit breaker.
- Ground-fault push-to-trip button works for testing ground fault with or without current flowing through the circuit breaker.
- Optional Modbus communications are functional, using a separate 24 Vdc power supply for the circuit breaker communications module. This separate 24 Vdc power supply is required to maintain the isolation between the trip unit and communications.

The ground-fault push-to-trip is also functional if a Hand-Held Test Kit or Full-Function Test Kit is powering the trip unit.

⚠ CAUTION

HAZARD OF SHOCK, ARC FLASH OR EQUIPMENT DAMAGE

Trip unit and communication module must use separate power supplies.

Failure to follow this instruction can result in personal injury or equipment damage.

The trip unit display can be powered by a 24 Vdc external power supply.

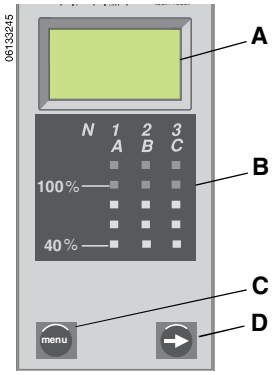
Section 2— Ammeter

Display



NOTE: The ammeter display will function only if the trip unit is powered. The trip unit is powered by the circuit breaker carrying more than 0.20 x In of load current, by being connected to a 24 Vdc external power supply, or by having the Full-Function Test Kit or Hand-Held Test Kit connected and on. Even with external power supplied, current through the circuit breaker must exceed 0.20 x In for the ammeter reading to be accurate to within 1.5%.

A. Alphanumeric screen: Displays ammeter information
B. Bar graph: Displays currents using an LED bar graph
C. Menu button: Used to navigate between the various menus
D. Scroll button: Used to scroll to the next screen in the menus

The default display is the current value of the phase at the highest load.

If no information is displayed, contact the local field office.

Figure 14 – Ammeter

Ammeter Measurements

Micrologic A trip units measure the true RMS value of currents. They provide continuous current measurement from 0.2 to 20 x In with an accuracy of 1.5% (including sensors). No auxiliary source is needed where I > 0.2 x In. The optional external power supply (24 Vdc) makes it possible to display currents where I < 0.2 x In.

A digital LCD screen continuously displays the most heavily loaded phases (Imax) or displays the Ia, Ib, Ic, Ig, and (on 4-pole circuit breakers only) In stored current and setting values by successively pressing the navigation button.

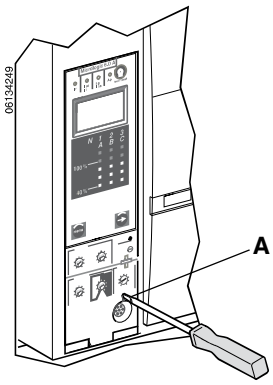
Trip Unit Operation Verification

Use a test kit connected to the trip unit test plug receptacle (A) to verify trip unit is functioning as desired. See instructions shipped with test kit to perform verification tests.

Figure 37 – Verify Trip Unit Operation

Equipment Ground-Fault Trip Functions Testing



Paragraph 230-95 (c) of the National Electrical Code requires that all equipment ground-fault protection systems be tested when first installed.

With the circuit breaker closed, test the ground-fault (Micrologic 6.0A trip unit only) trip functions. For instructions on how to close circuit breaker, refer to the circuit breaker installation instructions shipped with the circuit breaker.

1. Press the ground-fault test button (A). Circuit breaker should trip.
2. If circuit breaker does not trip, contact the local field office.

NOTE: Trip unit must be powered to test ground-fault trip function. The trip unit is powered if the circuit breaker is carrying more than 0.20 x In of load current, if the 24 Vdc external power supply is connected or if the Full-Function Test Kit or Hand-Held Test Kit is connected and on.

Trip Unit Resetting

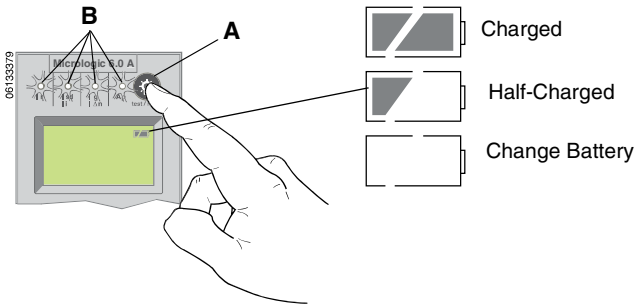
When the circuit breaker trips, the fault indicator will remain lit until the trip unit is reset.

Press the reset/test button (A) to reset the trip unit after trip.

Do not return circuit breaker to service until cause of trip is determined. For more information, refer to the circuit breaker installation instructions shipped with the circuit breaker.

Figure 39 – Reset Trip Unit

Trip Unit Status Check



NOTE: Trip unit must be powered to test battery. The trip unit is powered if the circuit breaker is carrying more than 0.20 x In of load current, if the 24 Vdc external power supply is connected or if the Full-Function Test Kit or Hand-Held Test Kit is connected and on.

To check trip unit battery and trip indicators, press the test/reset button (A).

- All trip indicators (B) will light up
- Battery status will be displayed
- If no battery status is displayed, there is no battery installed.
- The battery bar graph reading is valid after the reset button has been released.
- If the battery bar graph shows the battery needs to be changed, use Square D battery catalog number S33593:

Section 4— Trip Unit Replacement

Trip unit replacement must be done by qualified persons, as defined by the National Electric Code, who are familiar with the installation and maintenance of power circuit breakers.

Before replacing trip unit, confirm that the circuit breaker is in good working condition. If the condition of the circuit breaker is unknown, do not proceed. For assistance in evaluating the condition of the circuit breaker, call Technical Support.

Read this entire section before starting the replacement procedure.

NOTE: If trip unit being replaced is a Micrologic 2.0, 3.0 or 5.0 trip unit, order connector block S33101 and circuit breaker or cradle wiring harness if necessary.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Failure to follow these instructions for installation, trip test and primary injection testing may result in the failure of some or all protective function.
- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- Replacement/upgrading of a trip unit in the field must be done by qualified persons, as defined by the National Electric Code, who are familiar with the installation and maintenance of power circuit breakers.
- Before replacing/upgrading trip unit, confirm that the circuit breaker is in good working condition. If the condition of the circuit breaker is unknown, do not proceed. For assistance in evaluating the condition of the circuit breaker, call Technical Support.
- If the circuit breaker fails to function properly in any manner upon completion of the trip unit installation, immediately remove the circuit breaker from service and call Field Services.
- Turn off all power supplying this equipment before working on or inside equipment. Follow instructions shipped with circuit breaker to disconnect and reconnect circuit breaker.
- Replace all devices, doors and covers before returning equipment to service.

Failure to follow this instruction will result in death or serious injury.

Required Tools

- Torque-controlled screwdriver, set at 7 in-lbs (0.8 N•m) ± 10% (Lindstrom torque driver MAL500-2 or equivalent)
- Micrologic Full-Function Test Kit (part number S33595)

Preparation

Record Switch Settings

Record all trip unit switch settings for later use.

Circuit Breaker Disconnection

Disconnect circuit breaker as directed in the circuit breaker instruction bulletin shipped with the circuit breaker. The circuit breaker must be completely isolated. (For a drawout circuit breaker, place circuit breaker in the disconnected position.

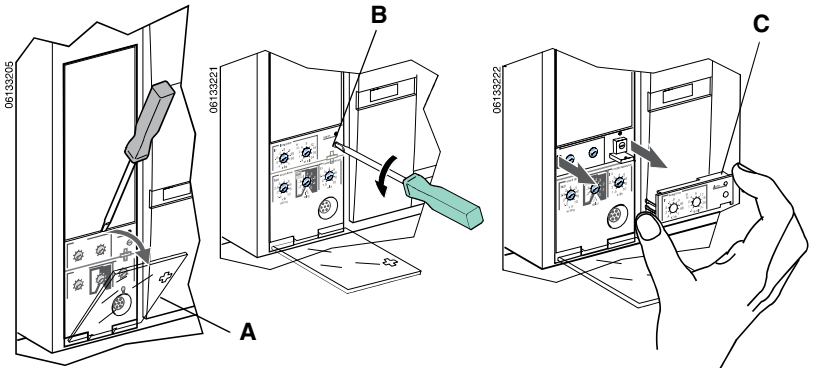
For a fixed-mounted circuit breaker, all voltage sources, including auxiliary power, must be disconnected.)

Circuit Breaker Accessory Cover Removal



Remove circuit breaker accessory cover as directed in the Install Accessories section of the circuit breaker instruction bulletin shipped with the circuit breaker.

Rating Plug Removal

A small Phillips screwdriver is needed to remove the adjustable rating plug.

1. Open switch cover (A).
2. Unscrew adjustable rating plug mounting screw (B).
3. Remove adjustable rating plug (C). Save for installation in replacement trip unit.

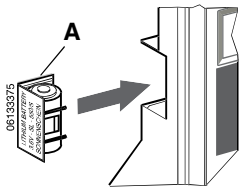
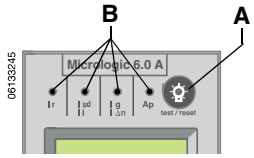
Trip Unit Replacement



Battery Installation

If a new trip unit is being installed, install the trip unit battery.

Install battery holder with battery (A) in trip unit, observing the correct polarity as indicated on the battery compartment.



NOTE: Battery holder with battery is located under the side flap in the cardboard box the trip unit is shipped in.

Figure 43 – Install Battery

Press test/reset button (A). All four indicator lights (B) should light. If they do not light, check polarity of battery and retest. If indicator lights still do not light up when test/reset button is pressed, stop installation and contact the local sales office for factory authorized service

Trip Unit Installation

1. Inspect trip unit connector pins and surfaces. If there is any damage, misaligned pins, or contamination, stop installation and contact the local sales office for factory authorized service.
2. Inspect trip unit mounting base on the circuit breaker. Clear any debris from area and check that all accessory wiring is properly routed for the trip unit being installed. If there is any damage or contamination, stop installation and contact the local sales office for factory authorized service.
3. For Masterpact NW circuit breaker only: Manually depress trip unit interlock (A) and hold it in place during steps 4–6.
4. Align guide rail (B) on bottom of trip unit with guide rail slot (C) on trip unit mounting base in circuit breaker and gently slide the trip unit in until it stops.

NOTE: The Masterpact NT and NW trip unit mounting bases are shock mounted and therefore can flex slightly.

Figure 45 – Install Trip Unit

NOTICE
HAZARD OF EQUIPMENT DAMAGE Check installation of trip unit to assure proper connections and seating. **Failure to follow this instruction can result in equipment damage or improper circuit breaker tripping.**

5. Align the trip unit so top mounting screw (A) aligns with the top threaded insert and start the screw by turning the screw two full rotations.
6. Use a torque-controlled screwdriver to drive the bottom screw (B) to 7 in-lbs (0.8 N•m) ± 10%. The back of the trip unit must be flush with the trip unit mounting base.
7. Use a torque-controlled screwdriver to drive the top screw to 7 in-lbs (0.8 N•m) ± 10%. Mounting tab must be flush with the mounting standoff and sensor plug.

NOTE: The face of the closed switch cover must be flush with adjoining mounting base surfaces. If these surfaces are not flush, stop installation and contact the local sales office for factory authorized service.

NOTE: If you are upgrading from a Micrologic 2.0, 3.0 or 5.0 trip unit, the connector block must be ordered separately (Part Number S33101). See instructions shipped with the connector block for installation into circuit breaker.

8. Install connector block (C) into top of trip unit.

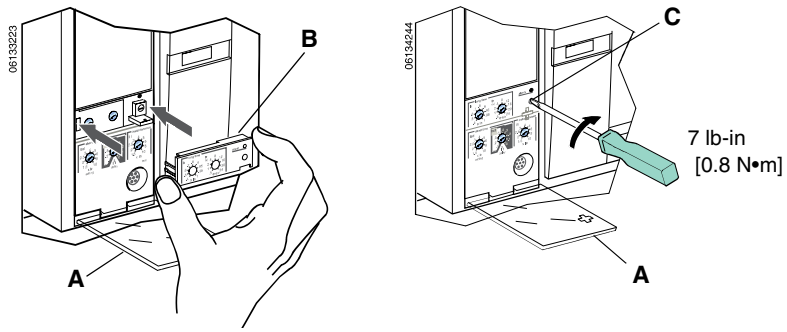

Figure 46 – Install Trip Unit

9. Install adjustable rating plug into the trip unit.
   a. Open switch cover (A) on new trip unit.
   b. Inspect mounting area for debris and contamination.
   c. Gently push adjustable rating plug (B) into new trip unit.
   d. Tighten adjustable rating plug mounting screw (C). The plug will be drawn into position flush with front face as screw is tightened.
10. Set trip unit switches to values recorded above or per coordination study results.
11. Close switch cover (A).

Trip Unit Installation Check

Secondary Injection Testing

Field installation of a trip unit requires secondary injection testing with the Full-Function Test Kit. to ensure that the newly-installed trip unit is functioning properly. The test will require opening and closing the circuit breaker. Follow the procedures outlined in the instruction bulletins shipped with the circuit breaker and the test kit.

1. Make sure the circuit breaker is isolated from all upstream and downstream devices.
2. Perform secondary injection testing as outlined in the instruction bulletin shipped with the test kit. Verify that all applicable trip unit functions are operating properly.
3. Repeat step 2 with the circuit breaker in the open position.

   NOTE: The test kit states that the circuit breaker should be closed when performing the test. Do not close the circuit breaker for this step.
4. If any test fails, do not put the circuit breaker into service and contact the local sales office for factory authorization service.

Primary Injection Testing

Primary injection testing is recommended to ensure that all trip system connections have been correctly made. Perform primary injection testing per the instructions in the Field Testing and Maintenance Guide, bulletin number 0600IB1201.

Check Accessory Operation

1. Installed accessories – Validate the proper operation of all installed accessories. See the corresponding accessory instruction bulletins for operational testing procedures.
2. Zone selective interlocking – If the circuit breaker is part of a ZSI system, follow the zone selective interlocking test procedures as outlined in the Full Function Test Kit instruction bulletin.
3. Communications – If communication modules exist, validate circuit breaker has re-established communications with the supervisor.

Trip Unit Setup

1. If an auxiliary power supply is being used for the Micrologic trip unit, reconnect the auxiliary power supply.
2. Reset the trip unit switches to original values, as recorded at the beginning of this section.

Circuit Breaker Reconnection

Reconnect circuit breaker as directed in the circuit breaker instruction bulletin shipped with the circuit breaker.

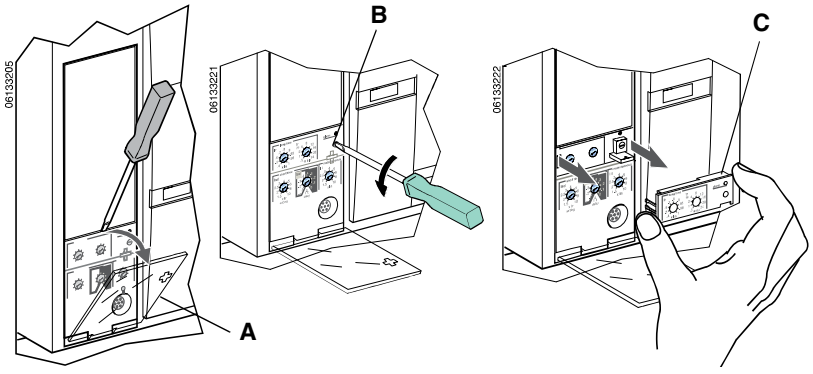
Section 5— Adjustable Rating Plug Replacement

NOTE: To select correct replacement rating plug, see the product catalog.

NOTE: If adjustable rating plug is removed, the circuit breaker will default to a long-time pickup rating of 0.4 x In and a long-time delay at whatever setting was selected before the rating plug was removed.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH



- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must be installed and serviced only by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment. Follow instructions shipped with circuit breaker to disconnect and reconnect circuit breaker.
- Replace all devices, doors and covers before returning equipment to service.

Failure to follow this instruction will result in death or serious injury.

Rating Plug Removal

1. Open circuit breaker contacts:
   - — For Masterpact NT and NW circuit breakers, press the “Push to open” button on the circuit breaker.
   - — For other circuit breakers, move handle to the off (O) position.
2. Open switch cover (A).
3. Unscrew adjustable rating plug mounting screw (B).
4. Remove adjustable rating plug (C).

New Rating Plug Installation

1. Inspect mounting area for debris and contamination.
2. Gently push in new adjustable rating plug (A).
3. Tighten adjustable rating plug mounting screw (B).
4. Set the switches on the trip unit (see Section 3 —Operation).
5. Close switch cover (C).

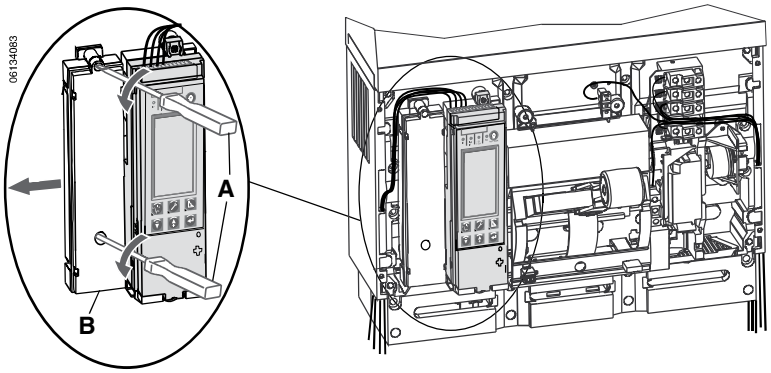
HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must be installed and serviced only by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment. Follow instructions shipped with circuit breaker to disconnect and reconnect circuit breaker.
- Replace all devices, doors and covers before returning equipment to service.

Failure to follow this instruction will result in death or serious injury.

Disconnect circuit breaker as directed in the circuit breaker instruction bulletin shipped with the circuit breaker.

Accessory Cover Removal



Remove circuit breaker accessory cover as directed in the Install Accessories section of the circuit breaker instruction bulletin shipped with the circuit breaker.

Withstand Module Shifting

NOTE: Some R-frame and NS1600b–NS3200 circuit breakers have a withstand module that needs to be moved to access the battery.

Loosen screws (A) securing withstand module (B). Swing module to side to access trip unit battery cover. Do not remove withstand module connector.

Hazard Categories and Special Symbols

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

ANSI

This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

IEC

⚠ DANGER

DANGER indicates a hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a hazardous situation which, if not avoided, **can result in** minor or moderate injury.

NOTICE

NOTICE is used to address practices not related to physical injury. The safety alert symbol is not used with this signal word.

NOTE: Provides additional information to clarify or simplify a procedure.

Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

FCC Notice

This equipment has been tested and found to comply with the limits for a Class A digital device, pursuant to part 15 of the FCC Rules. These limits are designed to provide reasonable protection against harmful interference when the equipment is operated in a commercial environment. This equipment generates, uses, and can radiate radio frequency energy and, if not installed and used in accordance with the instruction manual, may cause harmful interference to radio communications. Operation of this equipment in a residential area is likely to cause harmful interference in which case the user will be required to correct the interference at his own expense. This Class A digital apparatus complies with Canadian ICES-003.

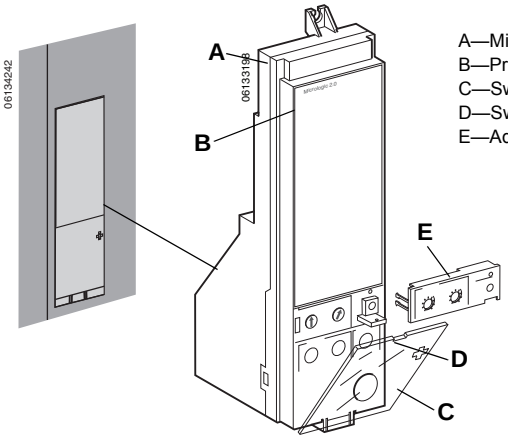
Section 1—General Information

Introduction



Micrologic™ trip units (A) provide adjustable tripping functions on electronic trip circuit breakers. The product name (B) specifies the level of protection provided by the trip unit.

Micrologic 3.0 Trip Unit

- Type of protection
  - 2—Basic IEC protection (LS0)
  - 3—Basic UL protection (LI)
  - 5—Selective protection (LSI)
- Trip unit series
  - 0—Indicates the first version

Micrologic trip units are field replaceable to allow for upgrading of the trip unit in the field. For complete information on available circuit breaker models, frame sizes, interrupting ratings, sensor plugs, rating plugs and trip units, see the product catalog.

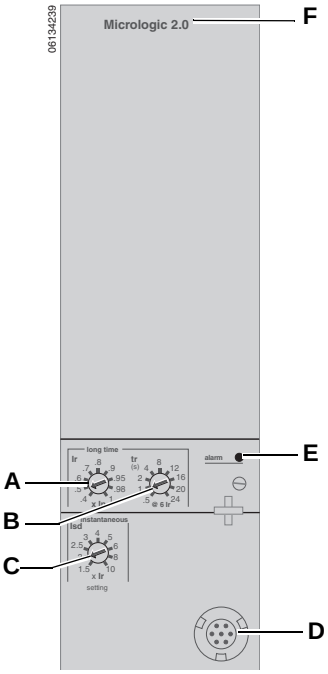
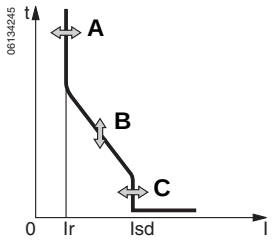
Trip Unit Settings

On the face of the trip unit are adjustable switches to allow changing of trip characteristics. Trip units are shipped with the long-time pickup switch set at 1.0 and all other trip unit adjustments set at their lowest settings.

Micrologic 2.0 Trip Unit



NOTE: For use with IEC circuit breakers only.



The Micrologic 2.0 trip unit provides basic IEC (LS0) protection.

Trip Unit Switches

Long-Time Protection

Long-time protection protects equipment against overloads.

- Long-time protection is standard on all trip units.
- The long-time pickup (Ir) (A) sets maximum current level (based on sensor plug rating In) which circuit breaker will carry continuously. If current exceeds this value, circuit breaker will trip after the preset time delay. The long-time pickup (Ir) is adjustable from 0.4–1.0 times the sensor plug rating (In).
- The long-time delay (tr) (B) sets the length of time that the circuit breaker will carry an overcurrent below the short-time or instantaneous pickup current level before tripping. See Table 1 for long-time delay settings.
- The overload indicator light (C) indicates that the Ir long-time pickup threshold has been exceeded.
- Both long-time pickup and long-time delay are on the field-replaceable adjustable rating plug. To change settings to more precisely match the application, various rating plugs are available. For instructions on replacing the rating plug, see Section 4—Adjustable Rating Plug Replacement.
- The In value can be changed by replacing the sensor plug below the trip unit. For further information, see the instructions packed with the sensor plug replacement kit.
- Long-time protection uses true RMS measurement.

Thermal imaging provides continuous temperature rise status of the wiring, both before and after the device trips. This allows the circuit breaker to respond to a series of overload conditions which could cause conductor overheating, but would go undetected if the long-time circuit was cleared every time the load dropped below the pickup setting or after every tripping event.

NOTE: If checking trip times, wait a minimum of 15 minutes after circuit breaker trips before resetting to allow the thermal imaging to reset completely to zero.

Figure 5: Long-Time Protection Switches

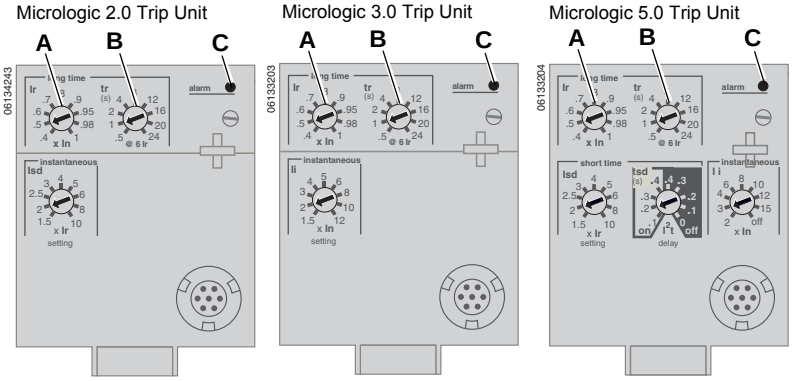

Table 1: Micrologic Trip Unit Long-Time Delay Values

Setting[1]	Long-Time Delay in Seconds[2]								
tr at 1.5 x Ir	12.5	25	50	100	200	300	400	500	600
tr at 6 x Ir	0.5	1	2	4	8	12	16	20	24
tr at 7.2 x Ir	0.34[3]	0.69	1.38	2.7	5.5	8.3	11	13.8	16.6

[1]In = sensor rating. Ir = In x long-time pickup. Trip threshold between 1.05 and 1.20 Ir.
[2]Time-delay accuracy +0/-20%
[3]For Micrologic 5.0 trip units, when tsd is set to 0.4 off or 0.4 on, then tr = 0.5 instead of 0.34.

Short-Time Protection

Short-time protection protects equipment against short circuits.

- Short-time protection is standard on 2.0 and 5.0 trip units. It is not available on 3.0 trip units.
- Short-time protection is based on the long-time pickup (Ir)
- The short-time pickup (Isd) (A) sets the current level (below instantaneous trip level) where the circuit breaker will trip after the preset time delay.
- The short-time delay (tsd) (B) sets the length of time that the circuit breaker will carry an overcurrent above the short-time pickup current level before tripping. It is adjustable on the 5.0 trip unit and factory set to zero on the 2.0 trip unit.
- The I^2t on/I^2t off option provides improved selectivity with downstream protective devices:
- With I^2t off selected, fixed time delay is provided.
  - — With I^2t on selected, inverse time I^2t protection is provided up to 10 x Ir. Above 10 x Ir, a fixed time delay is provided.
  - — Intermittent currents in the short-time tripping range which do not last sufficiently long to trigger a trip are accumulated and shorten the trip delay appropriately.
- Setting tsd to the 0 setting turns off time-delay features.
- Short-time protection uses true RMS measurement.
- Short-time delay can be adjusted to provide selectivity with a downstream circuit breaker.

Figure 6: Short-Time Protection Switches

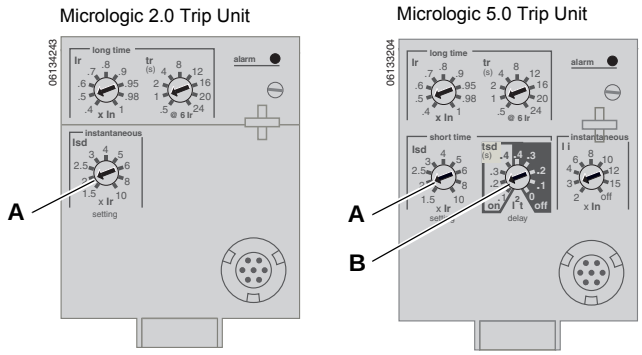

Table 2: Micrologic Trip Unit Short-Time Delay Values

Setting	Short-Time Delay				
I^2t off (Isd at 10 Ir) (seconds)	0	0.1	0.2	0.3	0.4
I^2t on (Isd at 10 Ir) (seconds)	–	0.1	0.2	0.3	0.4
tsd (min. trip) (milliseconds)	20	80	140	230	350
tsd (max. trip) (milliseconds)	80	140	200	320	500

Instantaneous Protection

Instantaneous protection protects equipment against short circuits with no intentional time delay.

- Instantaneous protection (Ii) (A) is standard on 3.0 and 5.0 trip units.*
- Instantaneous protection for 2.0 trip units is based on the circuit breaker sensor rating (Ir).
- Instantaneous protection for 3.0 and 5.0 trip units is based on the long-time delay pickup (In).
- Circuit breaker open command is issued as soon as threshold current is exceeded.
- Instantaneous protection for 3.0 and 5.0 trip units use peak current measurement. Instantaneous protection for 2.0 trip units use RMS current measurement.
- When instantaneous protection switch is set to off, the instantaneous protection is disabled.

*Instantaneous protection on 2.0 trip units is achieved by using short-time protection (Isd) with short-time delay factory set to 0 (zero).

Figure 7: Instantaneous Protection Switches

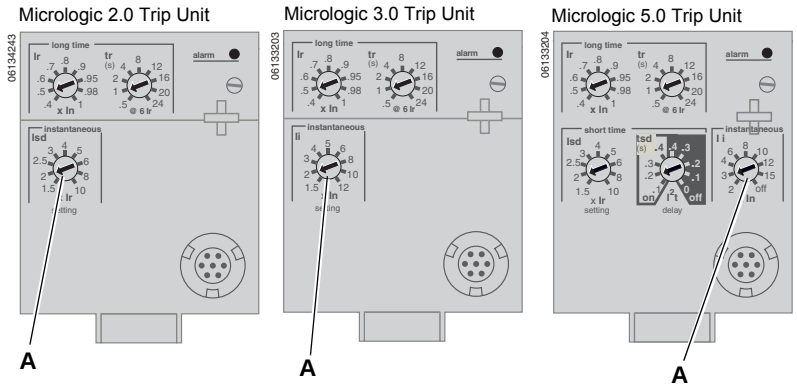

Table 3: Micrologic Instantaneous Values

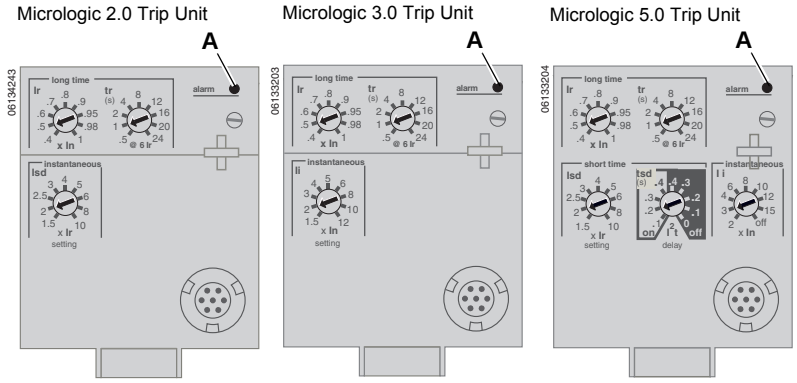

Setting	Interruption Current								
2.0 Isd (= Ir x..)	1.5	2	2.5	3	4	5	6	8	10
3.0 Ii (= In x..)	1.5	2	3	4	5	6	8	10	12
5.0 Ii (= In x..)	2	3	4	6	8	10	12	15	off

Ii = UL and ANSI instantaneous
Isd = IEC instantaneous (short-time with zero delay)
In = sensor rating
Ir = long-time pickup

Section 3—Trip Unit Replacement

Trip unit replacement must be done by qualified persons, as defined by the National Electric Code, who are familiar with the installation and maintenance of power circuit breakers.

Before replacing trip unit, confirm that the circuit breaker is in good working condition. If the condition of the circuit breaker is unknown, do not proceed. For assistance in evaluating the condition of the circuit breaker, call Technical Support.

Read this entire section before starting the replacement procedure.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH

- Failure to follow these instructions for installation, trip test and primary injection testing may result in the failure of some or all protective function.
- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- Replacement/upgrading of a trip unit in the field must be done by qualified persons, as defined by the National Electric Code, who are familiar with the installation and maintenance of power circuit breakers.
- Before replacing/upgrading trip unit, confirm that the circuit breaker is in good working condition. If the condition of the circuit breaker is unknown, do not proceed. For assistance in evaluating the condition of the circuit breaker, call Technical Support.
- If the circuit breaker fails to function properly in any manner upon completion of the trip unit installation, immediately remove the circuit breaker from service and call Field Services.
- Turn off all power supplying this equipment before working on or inside equipment. Follow instructions shipped with circuit breaker to disconnect and reconnect circuit breaker.
- Replace all devices, doors and covers before returning equipment to service.

Failure to follow this instruction will result in death or serious injury.

Required Tools

- Torque-controlled screwdriver, set at 7 in-lbs (0.8 N•m) ± 10% (Lindstrom torque driver MAL500-2 or equivalent)
- Micrologic Full-Function Test Kit (part number S33595)

Preparation

Record Switch Settings

Record all trip unit switch setting for later use.

Circuit Breaker Disconnection

Disconnect circuit breaker as directed in the circuit breaker instruction bulletin shipped with the circuit breaker. The circuit breaker must be completely isolated. (For a drawout circuit breaker, place circuit breaker in the disconnected position. For a fixed-mounted circuit breaker, all voltage sources, including auxiliary power, must be disconnected.)

Circuit Breaker Accessory Cover Removal

Remove circuit breaker accessory cover as directed in the Install Accessories section of the circuit breaker instruction bulletin shipped with the circuit breaker.

Rating Plug Removal

A small Phillips screwdriver is needed to remove the adjustable rating plug.

1. Open switch cover (A).
2. Unscrew adjustable rating plug mounting screw (B).
3. Remove adjustable rating plug (C). Save for installation in replacement trip unit.

Trip Unit Installation

1. Inspect trip unit connector pins and surfaces. If there is any damage, misaligned pins, or contamination, stop installation and contact the local sales office for factory authorized service.
2. Inspect trip unit mounting base on the circuit breaker. Clear any debris from area and check that all accessory wiring is properly routed for the trip unit being installed. If there is any damage or contamination, stop installation and contact the local sales office for factory authorized service.
3. For Masterpact NW circuit breaker only: Manually depress trip unit interlock (A) and hold it in place during steps 4–6 below.
4. Align guide rail (B) on bottom of trip unit with guide rail slot (C) on trip unit mounting base in circuit breaker and gently slide the trip unit in until it stops.

NOTE: The Masterpact NT and NW trip unit mounting bases are shock mounted and therefore can flex slightly.

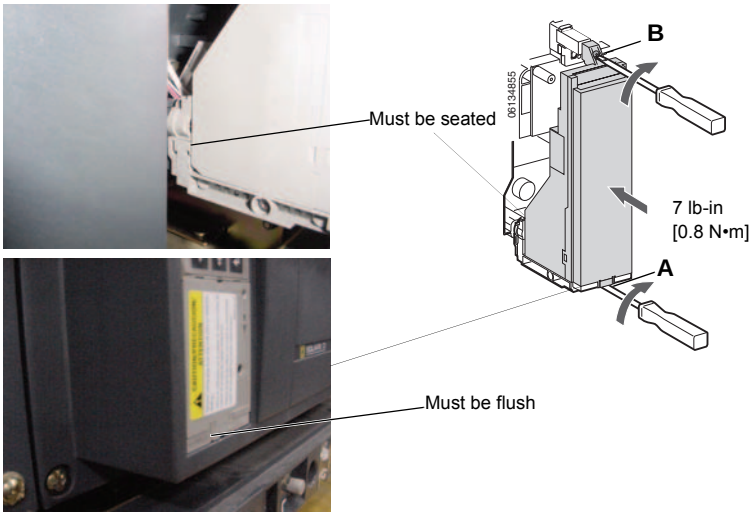
⚠ CAUTION

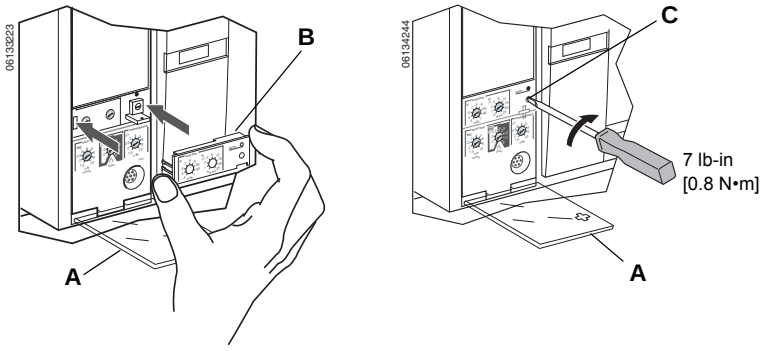
HAZARD OF EQUIPMENT DAMAGE



Check installation of trip unit to assure proper connections and seating.

Failure to follow this instruction can result in equipment damage or improper circuit breaker tripping.

5. Align the trip unit so top mounting screw (B) aligns with the top threaded insert and start the screw by turning the screw two full rotations.
6. Use a torque-controlled screwdriver to drive the bottom screw to 7 in-lbs (0.8 N•m) ± 10%. The back of the trip unit must be flush with the trip unit mounting base.
7. Use a torque-controlled screwdriver to drive the top screw to 7 in-lbs (0.8 N•m) ± 10%. Mounting tab must be flush with the mounting standoff and sensor plug.



NOTE: The face of the closed switch cover must be flush with adjoining mounting base surfaces. If these surfaces are not flush, stop installation and contact the local sales office for factory authorized service.

Figure 21: Install Trip Unit

8. Install adjustable rating plug into the trip unit.
   a. Open switch cover (A) on new trip unit.
   b. Inspect mounting area for debris and contamination.
   c. Gently push adjustable rating plug (B) into new trip unit.
   d. Tighten adjustable rating plug mounting screw (C). The plug will be drawn into position flush with front face as screw is tightened.
9. Set trip unit switches to values recorded above or per coordination study results.
10. Close switch cover (A).

Trip Unit Installation Check

Secondary Injection Testing

Field installation of a trip unit requires secondary injection testing with a Full-Function Test Kit. This will ensure that the newly-installed trip unit is functioning properly. The test will require opening and closing the circuit breaker. Follow the procedures outlined in the instruction bulletins shipped with the circuit breaker and the Full-Function Test Kit.

1. Make sure the circuit breaker is isolated from all upstream and downstream devices.
2. Perform secondary injection testing as outlined in the instruction bulletin shipped with the Full-Function Test Kit. Verify that all applicable trip unit functions are operating properly.
3. Repeat step 2 with the circuit breaker in the open position.

   NOTE: The test kit will state that the circuit breaker should be closed when performing the test. Do not close the circuit breaker for this step.
4. If any test fails, do not put the circuit breaker into service and contact the local sales office for factory authorization service.

Primary Injection Testing

Primary injection testing is recommended to ensure that all trip system connections have been correctly made. Perform primary injection testing per the instructions in the Field Testing and Maintenance Guide, bulletin 0600IB1201.

Trip Unit Setup

Reset the trip unit switches to original values, as recorded at the beginning of this section.

Circuit Breaker Reconnection

Reconnect circuit breaker as directed in the circuit breaker instruction bulletin shipped with the circuit breaker.

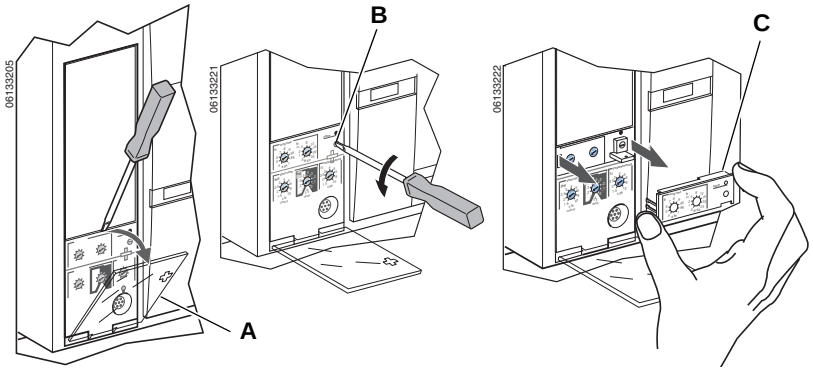
Section 4—Adjustable Rating Plug Replacement

NOTE: To select correct replacement rating plug, see the product catalog.

NOTE: If adjustable rating plug is removed, the circuit breaker will default to a long-time pickup rating of 0.4 x In and a long-time delay at whatever setting was selected before the rating plug was removed.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION OR ARC FLASH



- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must be installed and serviced only by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment. Follow instructions shipped with circuit breaker to disconnect and reconnect circuit breaker.
- Replace all devices, doors and covers before returning equipment to service.

Failure to follow this instruction will result in death or serious injury.

Rating Plug Removal

1. Open circuit breaker contacts:
   - — For NT and NW circuit breakers, press the “Push to open” button on the circuit breaker.
   - — For other circuit breakers, move handle to the off (O) position.
2. Open switch cover (A).
3. Unscrew adjustable rating plug mounting screw (B).
4. Remove adjustable rating plug (C).

HAZARD CATEGORIES AND SPECIAL SYMBOLS

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to potential personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates an imminently hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a potentially hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a potentially hazardous situation which, if not avoided, **can result in** minor or moderate injury.

CAUTION

CAUTION, used without the safety alert symbol, indicates a potentially hazardous situation which, if not avoided, **can result in** property damage.

NOTE: Provides additional information to clarify or simplify a procedure.

PLEASE NOTE

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

Section 1—Introduction

This bulletin contains instructions for the proper installation, operation, and maintenance of Square D® Integrated Power and Control Solutions (IPaCS™) Integrated Power Center 2 (IPC2™) equipment manufactured by Schneider Electric. The purchaser's engineering, installation, and operating staff supervisors should familiarize themselves with this bulletin and become acquainted with the appearance and characteristics of each piece of equipment mounted or contained in the IPC2.

These instructions and procedures apply to IPC2 installations by Schneider Electric. When special features or non-standard components are incorporated in the IPC2, detailed instructions for these components are included in the instruction material holder.

Inspection and Packaging

Every IPC2 is carefully inspected and packaged at the assembly plant. Construction of the IPC2 is checked, both structurally and electrically, for compliance with all specifications, codes, and standards. After a complete inspection, the IPC2 is prepared for shipment. The factory order number, the identification number, and the shipping weights are plainly marked on each shipping block.

Document Replacement

Contact your nearest Schneider Electric field office to replace lost or damaged wiring diagrams and instruction sheets. Use the factory order number as a reference.

Section 2—Safety Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must be installed and serviced only by qualified personnel.
- Perform such work only after reading and understanding all of the instructions contained in this bulletin.
- Turn off all power supplying this equipment before working on or inside equipment.
- Before performing visual inspections, tests, or maintenance on this equipment, disconnect all sources of electric power. Assume all circuits are live until they are completely de-energized, tested, and tagged. Pay particular attention to the design of the power system. Consider all sources of power, including the possibility of backfeeding.
- Always use a properly rated voltage sensing device to confirm power is off.
- Handle this equipment carefully and install, operate, and maintain it correctly in order for it to function properly. Neglecting fundamental installation and maintenance requirements may lead to personal injury, as well as damage to equipment or other property.
- Disconnect the neutral connection at any TVSS or other electronic device prior to performing electrical insulation resistance tests; reconnect to the device after testing.
- Carefully inspect your work area and remove any tools and objects left inside the equipment.
- Replace all devices, doors, and covers before turning on power to this equipment.
- All instructions in this bulletin assume that the customer has taken these measures before performing maintenance or testing.

Failure to follow these instructions will result in death or serious injury.

Section 3—Receiving, Handling, and Storing

Receiving

Upon receipt, check the packing list against the equipment received to ensure the order and shipment are complete. Also upon receipt, immediately inspect the IPC2™ shipping blocks for any damage that may have occurred in transit. If damage is found or suspected, file a claim with the carrier immediately and notify the nearest Schneider Electric representative. Claims for shortages or errors must be made in writing to Schneider Electric within 60 days after delivery. Failure to give such notice will constitute unqualified acceptance and a waiver of all such claims by the purchaser.

Delivery of equipment to a carrier at any of the Schneider Electric plants or other shipping points constitutes delivery to the purchaser regardless of freight payment and title. All risk of loss or damage pass to the purchaser at that time.

For details concerning claims for equipment shortages and other errors, refer to Schneider Electric “Terms and Conditions of Sale.”

Handling

CAUTION

HAZARD OF EQUIPMENT DAMAGE

Do not lay the NEMA 1 enclosed IPC2 equipment on its back or front. Do not lay the NEMA 1 enclosed IPC2 equipment on its side during transit to the job site. When necessary at the job site, the NEMA 1 enclosed IPC2 equipment may be carefully and gently laid onto its side. The NEMA 1 enclosed IPC2 equipment should be returned to its upright position as soon as possible. Then inspect the structure and its contents to ensure all components and insulators remained undamaged and secured before continuing the installation of the IPC2 equipment.

All IPC2 equipment with drip hoods or with NEMA 3R enclosures must always be kept upright during handling.

Failure to follow these instructions can result in equipment damage.

Ensure that proper equipment, such as an overhead crane, is available at the installation site to handle the IPC2.

The shipping weight of each shipping block is marked on the packing list. Verify the lifting capacity of the equipment being used to handle the IPC2 in accordance with the shipping weight of each shipping block. Whenever possible, keep the NEMA 1 enclosed IPC2 equipment upright during handling. If it is necessary to lay this equipment down, see the caution statement on this page for instructions. All IPC2 equipment with drip hoods or with NEMA 3R enclosures must always be kept upright during handling.

Schneider Electric recommends using an overhead crane, lifting eyebolts, and cables or chains to handle the NEMA 1 enclosed IPC2. This method and alternative handling methods are discussed in this section.

Handling NEMA 1 IPC2 Enclosures with Lifting Eyebolts

Schneider Electric provides lifting eyebolts as standard equipment for NEMA 1 enclosed IPC2 shipping blocks. Instruction labels on each shipping block include drawings and written instructions outlining the proper use of the lifting eyebolts (Figure 1). Use rigid spreaders or a spanner bar to provide vertical lift on the lifting eyebolts. This will help prevent damage to the frame or finish.

NOTE: For NEMA 1 enclosures with drip hoods, see “Handling NEMA 3R Enclosures or NEMA 1 IPC2 Enclosures with Drip Hoods” on page 9.

Figure 1: Lifting with an Overhead Crane, Lifting Eyebolts, and Cables or Chains

Front View **Side View**

Follow these instructions to handle the NEMA 1 enclosed IPC2:

1. Use load-rated cables or chains with safety hooks or shackles. Do not pass cables or chains through holes in lifting means.
2. Use a load-rated spreader beam to prevent structure damage. Rig so that the minimum angle between the lifting cables or chains and equipment top is 45 degrees.

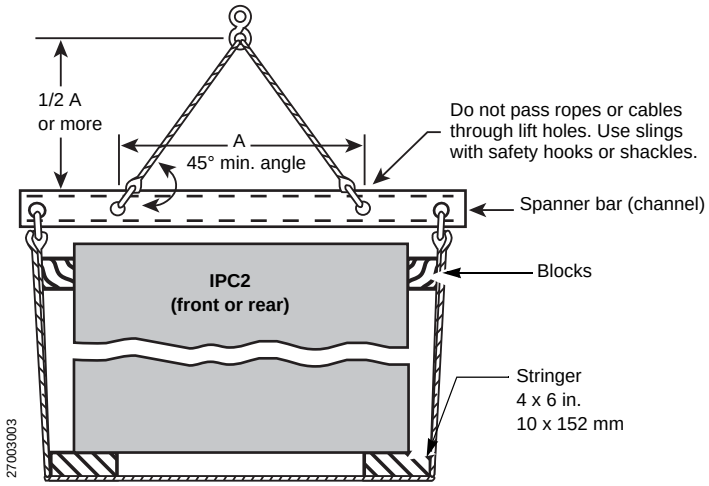
Handling NEMA 3R Enclosures or NEMA 1 IPC2 Enclosures with Drip Hoods

Rollers or slings may be used to handle the shipping blocks. When elevating a shipping block without the use of the lifting eyebolts, an overhead crane equipped with either of the following may be used:

- Load rated chain coupled to a sling rigging
- Load rated wire cable with safety hooks and shackles

Wrap the sling completely around the IPC2 and shipping stringers (see Figure 3).



⚠ WARNING

HAZARD OF EQUIPMENT DAMAGE—TOP HEAVY LOAD

Stabilize the shipping block to reduce the possibility of tipping.

Failure to follow these instructions can result in death or serious injury.

Figure 3: IPC2 in Sling Rigging

A forklift is an alternative method of handling the IPC2.

NOTE: Always check the fork lengths to ensure that the forks extend under the entire IPC2. Carefully balance the load, and always use a safety strap when handling or moving an IPC2 with a forklift (Figure 4).

Storing

When storing the IPC2 before installation, cover the top and any openings of the equipment during the construction period to protect the IPC2 from dust and debris.

If the IPC2 is not installed and energized immediately, store it in a clean, dry space with a consistent temperature to prevent condensation. Store the IPC2 indoors, if possible. Preferably, store it in a heated building with adequate air circulation and protect it from dirt, fumes, water, and physical damage. Storing the IPC2 outdoors may cause harmful condensation inside the IPC2.

NOTE: Install portable electric heaters of approximately 250 watts per vertical section in both indoor-type and rainproof-type IPC2 enclosures for adequate protection during storage.

Before energizing the space heaters, remove all loose packing or flammable materials inside the IPC2. Outdoor IPC2 equipment is not weather-resistant until completely and properly installed; treat them the same as indoor IPC2 equipment until after installation.

Section 4—Installation

Correct installation of IPC2™ equipment is essential for proper operation of all IPC2 components. Study the associated instruction books and all drawings carefully. In most cases, all drawings are sent to the purchaser before an IPC2 is shipped to enable adequate advance planning.

NOTE: While installing IPC2 equipment, do not use the top of the IPC2 as a support for the weight of the installer.

Location

Find the designated area on the building floor plan where the IPC2 will be installed. The location chosen for installation should provide working clearances complying with Section 110-26 of the National Electrical Code® (NEC®) or Section 2-308 of the Canadian Electrical Code (CEC) Part 1. IPC2 equipment requires field connections, including mains, branches, and ground bus, to be accessible and maintainable from the front.

Foundation Preparation

The floor or foundation must be strong enough to support the weight of the IPC2 without sagging. The surrounding floor area should gently slope toward a drain.

NOTE: For seismic qualifications, read the section “Anchoring the IPC2 for Seismic Qualifications” on page 17 before pouring the floor or foundation.

IPC2 equipment is assembled on true and level floors at the assembly plant. To ensure correct alignment with adjoining equipment, the mounting pad or final installation site must be smooth and level. If parallel steel floor channels are imbedded for mounting the IPC2, take extra care to ensure the floor channels are level over their entire length to avoid distortion of the IPC2 structure. Each channel should be level with the finished floor.

When pouring the foundation, make provisions for conduits entering the IPC2 from below and carrying the incoming and/or outgoing cables, control wiring, and ground cable. The bottom view in the equipment drawing shows the available conduit area for correct layout.

Conduits should project above the finished floor by about 2.00 in. (51 mm). However, to simplify moving the shipping blocks into place, install the conduits flush with the concrete and, after the blocks are in their final position, add the appropriate extension sleeves. Otherwise, raising the shipping block on timbers or lifting it by a crane to clear the conduit hubs will be necessary.

NOTE: Before pouring the foundation, consider installing additional conduits for future circuits.

© 2005–2010 Schneider Electric All Rights Reserved

IPC2 Preparation

- Remove dirt and debris from the foundation and surrounding area before moving the IPC2 into final position.
- After the IPC2 has been moved to its final installation site, take each shipping block off its shipping stringers.
- Remove all packing materials.

General Installation

Install the IPC2 into its final position by leveling progressively each section and bolting the frames together, if separated. Position shipping sections as follows:

1. Maneuver each shipping section into the desired position using the procedures under “Handling” on page 6.
2. Carefully lower the equipment over the conduit stubs to comply with the “available conduit area” as shown in the bottom view of the equipment drawings. Otherwise, there may not be sufficient cable bending space.
3. Level the shipping section.
4. After the installation of each section is complete, make the ground bus splice connection to the preceding section before installing the next section.

CAUTION

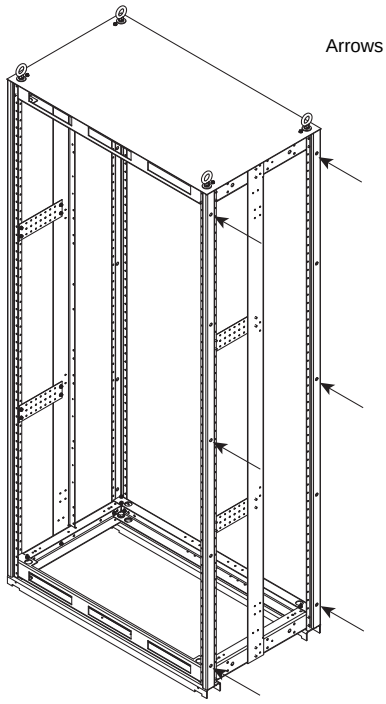
HAZARD OF EQUIPMENT DAMAGE

Level and align adjacent shipping sections with one another. Ensure proper alignment of horizontal main through bus and proper splice bus connections.

Failure to follow these instructions can result in equipment damage.

Joining Shipping Sections—Indoor IPC2 and Switchboards

1. Position each adjacent section, carefully leveling and aligning it with the previous section.
2. Open or remove the front and rear doors and panels, providing access to bolt adjacent shipping sections together.
3. Six bolts (3/8-16 x 1 inch) are provided. Place the bolts through the existing holes in the front and rear vertical corner channels to join adjacent sections (Figure 5).
4. Make the ground bus splice connections to the preceding section. See “Ground Bus Splice Connections Between IPC2 and Power-Style® QED Switchboards” on page 13.
5. Replace and secure all front and rear doors and panels removed in step 2.



⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must be installed and serviced only by qualified personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors, and covers before turning on power to this equipment.

Failure to follow these instructions will result in death and serious injury.

Joining Shipping Sections—Outdoor IPC2 and Switchboards

1. Remove the center top cap (Figure 6) from the left-hand section, and retain all hardware for reuse.

Figure 6: Joining Adjacent Sections—Outdoor IPC2 and Switchboards

2. When possible, open or remove the front and rear doors and panels, providing access to bolt adjacent shipping sections together.
3. Remove three 0.50-in. (13 mm) diameter knockouts from the front vertical corner channel and three from the rear vertical corner channel (a total of six per frame side) as indicated by the arrows in Figure 6. Ensure the knockouts do not fall into the structure.
4. Position each adjacent section, carefully leveling it and aligning it with the previous section.
5. Six bolts (3/8-16 x 1 inch) are provided. Place them through the holes created in step 3 to join adjacent sections. See Detail B.
6. Make the ground bus splice connections to the preceding section. See “Ground Bus Splice Connections Between IPC2 and Power-Style® QED Switchboards” on page 13.
7. Replace the center top cap removed in step 1. See Figure 6, Detail A.
8. If applicable, replace and secure all the front and rear doors and panels removed in step 2.

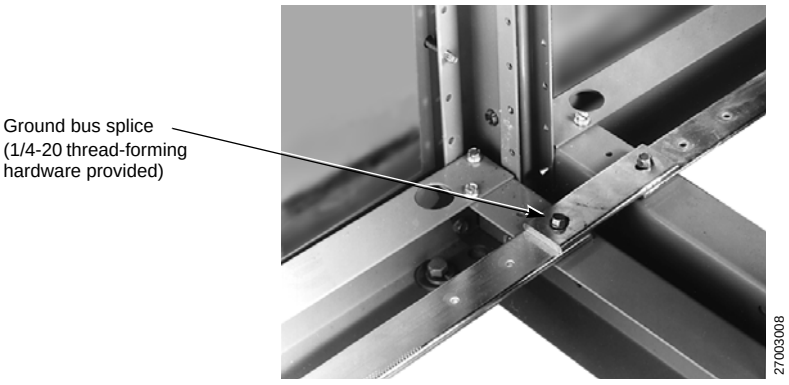
⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH



- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must be installed and serviced only by qualified personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors, and covers before turning on power to this equipment.

Failure to follow these instructions will result in death and serious injury.

Align and secure the ground bus splice connection between shipping sections. Torque connections to 100 lb-in (11 N•m). See Figure 7.

NOTE: Proper installation is essential for equipment ground-fault systems.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must be installed and serviced only by qualified personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors, and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Preparing the IPC2

NOTE: Before joining shipping blocks, ensure the IPC equipment is installed per the Integrated Power Center instruction bulletin no. 80043-056-__.

1. Remove dirt and debris from the foundation and surrounding area before moving the IPC2 enclosure into its final position.
2. After the IPC2 enclosure has been moved to its final installation site, take the equipment off its shipping stringers.

Joining Shipping Sections

1. Remove the side covers from the IPC2 enclosure to access the vertical support. Open or remove the front doors of the IPC to access the side panels.
2. Position the IPC2 enclosure and IPC sections adjacent to one another, carefully leveling and aligning the rear of each section.

Figure 8: IPC2 and IPC Shipping Sections

3. Locate and move any factory-installed cables through the side openings into the appropriate sections.
4. Bolts (1/4-20 x 1 inch), washers, and nuts are provided in the IPC structure. Seven sets of hardware will be used to join the sections. Align the section splicing holes in the front of the IPC side panel with the corresponding holes in the IPC2 vertical support.
5. Place the bolts through the holes in the IPC2 vertical support and IPC side panels to join the adjacent sections (Figure 8). Secure each bolt with a washer and nut until the connection is finger-tight.
6. Torque the hardware to 72 lb-in (8 N•m) to complete bolting the sections together.
7. Connect any factory-installed cables per Table 3 on page 32.
8. Replace the side covers on the IPC2 enclosure.

Making Ground Cable Splice Connections

1. Align and secure the ground cable connection between the IPC shipping sections per the *Integrated Power Center* instruction bulletin (see Figure 9).

   NOTE: Proper installation is essential for equipment ground-fault systems.
2. Locate the ground lug on the horizontal ground bus bar in the bottom of the IPC2 enclosure.
3. Place the stripped end of the ground cable from the IPC sections into the lug on the IPC2 ground bar (Figure 9).
4. Torque the ground cable connection per Table 3 on page 32.
5. Replace the IPC door, and reinstall the side covers on the IPC2 enclosure if not already completed.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must be installed and serviced only by qualified personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors, and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

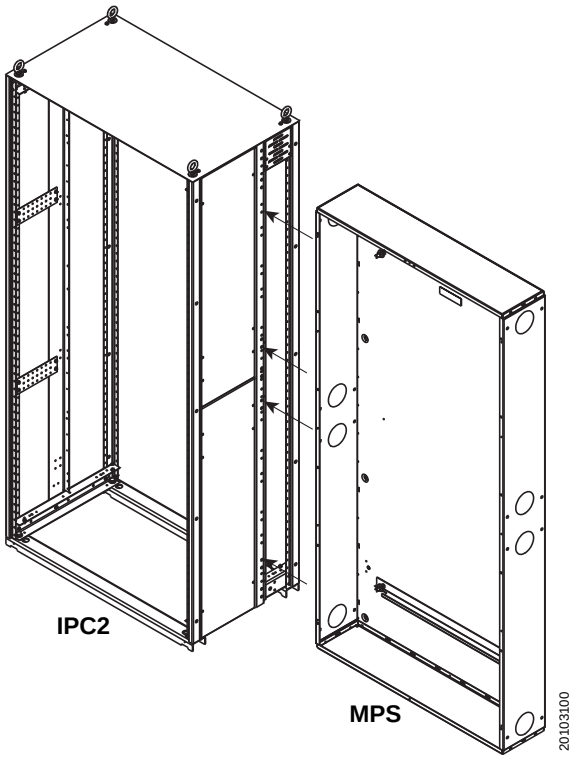
Preparing the IPC2



NOTE: Before joining shipping blocks, ensure the MPS equipment is positioned in its final location.

1. Remove dirt and debris from the foundation and surrounding area before moving the IPC2 enclosure into its final position.
2. After the IPC2 enclosure has been moved to its final installation site, take the equipment off its shipping stringers.

Joining Shipping Sections

1. Remove the side covers from the IPC2 enclosure to access the vertical support. Remove the front covers of the MPS to access the side panels of adjacent sections.
2. Position the IPC2 enclosure and MPS sections adjacent to one another, carefully leveling and aligning the rear of each sections.

Figure 10: IPC2 and MPS Shipping Sections

3. Locate and move any factory-installed cables through the side openings into the appropriate sections.
4. Bolts (3/8-16-x 1 inch), washers, and nuts are provided in the MPS structure. Four sets of hardware will be used to join the sections. Align the section splicing holes in the front of the MPS side panel with the corresponding holes in the IPC2 vertical support.
5. Place the bolts through the holes in the IPC2 vertical support and MPS side panels to join the adjacent sections (Figure 10). Secure each bolt with a washer and nut until the connection is finger-tight.
6. Torque the hardware to 72 lb-in (8 N•m) to complete bolting the sections together.
7. Connect any factory-installed cables per Table 3 on page 32.
8. Replace the side covers on the IPC2 enclosure.

Making Ground Cable Splice Connections

1. Run ground cable from the MPS ground bar to the IPC2 enclosure ground bar (see Figure 11).

   NOTE: Proper installation is essential for equipment ground-fault systems.

2. Locate the ground lug on the horizontal ground bus bar in the bottom of the IPC2 enclosure.
3. Place the stripped end of the ground cable into the lug on the IPC2 ground bar (Figure 11).
4. Torque the ground cable connection per Table 3 on page 32.
5. Replace the MPS covers, and reinstall the side covers on the IPC2 enclosure if not already completed.

Anchoring the IPC2 for Seismic Qualifications

IPC2 equipment that is seismically certified has been qualified to the site-specific seismic requirements of the listed model building codes and/or standards. Optional construction features may be required, depending on the location of the installation and the particular code and/or standard of interest. Seismic certificates of compliance are provided with all seismically-certified IPC2 equipment. To maintain the validity of this certification, the installation instructions provided in this bulletin must be followed.

© 2005–2010 Schneider Electric All Rights Reserved

Responsibility for Mitigation of Seismic Damage

For the purposes of the model building codes, IPC2 equipment is considered as nonstructural building components. Equipment capacity was determined from tri-axial seismic shake table test results as defined in the International Code Counsel Evaluation Service (ICCES) Acceptance Criteria for Seismic Qualification Testing of Nonstructural Components (AC156). Unless otherwise indicated, an equipment importance factor of 1.5 (Ip =1.5) was used, indicating that equipment functionality was verified before and after shaker table seismic simulation testing. This importance factor is indicative of critical facilities where maximizing the probability of post event functionality is a priority. AC156 is published by the ICC ES and has been recognized by the Building Seismic Safety Council (BSSC) as an appropriate methodology in the 2003 National Earthquake Hazard Reduction Program (NEHRP) Commentary (FEMA 450 Part 2). The National Institute of Building Sciences established the BSSC in 1979 to develop and promote regulatory provisions for earthquake risk mitigation at the national level.

Incoming and outgoing cable and conduit must also be considered as related but independent systems. They must be designed and restrained to withstand the forces generated by the seismic event without increasing the load transferred to the equipment. For applications where seismic hazard exists, bottom entry and/or exit of cable and conduit is preferred. This system must be capable of transferring the loads created to the load-bearing path of the building structural system.

Maintaining Seismic Certification

Seismic qualification of nonstructural components by Schneider Electric is just one link in the total chain of responsibility required to maximize the probability that the equipment will be intact and functional after a seismic event. During a seismic event, the equipment must be able to transfer the loads that are created through the mounting pad and anchorage to the load-bearing path of the building structural system.

The structural civil engineer or design engineer of record is responsible for detailing the equipment connection and anchorage requirements for the given installation. The installer and manufacturers of the anchorage restraint system are responsible for assuring that the mounting requirements are met. Schneider Electric is not responsible for the specification and performance of these systems.

Anchoring IPC2 for Seismic Applications

Formed base channels run the width of the section. The channels and connecting braces provide a 0.62-in. (16 mm) minimum diameter hole for fastening the section to the floor. To properly anchor the IPC2 to the floor, use all four mounting locations for 24-in. deep NEMA 1 enclosures, all six mounting locations for 36-in. deep NEMA 1 enclosures and 35-in. deep NEMA 3R enclosures, and all eight mounting locations for 47-in. deep NEMA 3R enclosures and all corner sections. Use ½-in. (12.7 mm) diameter anchor bolts (Grade 5 minimum, provided by others) for the installation of equipment. Use one 1.25-in (31.75 mm) outer diameter Grade 5 belleville washer (Square D part no. 23903-33201, stored inside each seismically qualified structure next to the front bottom base channel) under the head of each bolt or anchor nut. To develop full strength of the anchor, torque the hardware to the value specified by the anchor manufacturer or seismic restraint detailing supplied by the Structural Civil Engineer of record for the project.

Additionally, each NEMA 1 enclosed section includes two rear top-located eyebolts that may be removed to allow the user to attach two upper lateral braces (braces and hardware supplied by others) to the IPC2 structure for top structural restraint.

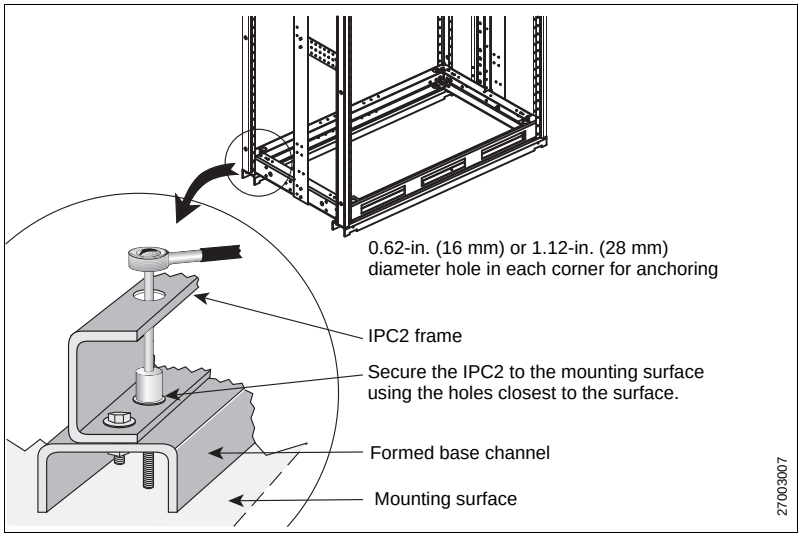
© 2005–2010 Schneider Electric All Rights Reserved

Top structural restraint is required for all IPC2 equipment installed:

- where the site-specific 0.2 second spectral ground motion exceeds 2.67 g's (as determined from the code-referenced ground motion maps or the site-specific seismic hazard engineering study),
- or when displacement at the top of the equipment cannot be tolerated,
- or for all IPC2 corner sections used for seismic applications.

To develop full strength of the upper structural anchor, install and torque the hardware as specified by the anchor manufacturer or seismic restraint detailing supplied by the Structural Civil Engineer of record for the project.

NOTE: Most of the anchoring hardware is not furnished with the IPC2 equipment, with the exception of the Grade 5 belleville washer (Square D part no. 23903-33201) mentioned above.



After the IPC2 and adjacent equipment are properly joined together and the entire structure is bolted to the floor, install the incoming service conductors and load side cables. During an earthquake, the top of the IPC2 can move in any direction. Any top incoming cables must accommodate this motion. The IPC2 enclosure (particularly the top) should not be used to mount exterior equipment.

Anchoring the IPC2

Although sections are freestanding, a hard bump or shifting movement can result in damage to the splice joints between sections and conduit hubs connected to the sections. Therefore, each vertical section must be anchored to the floor.

Formed base channels run the width of the shipping section. For fastening the section to the floors, the channels have 0.62-in. (16 mm) diameter holes for seismic applications or 1.12-in. (28 mm) diameter holes for non-seismic applications (see Figure 12 below). Anchor each section to the floor with 1/2-in. diameter (Grade 2 minimum) bolts with flat washers and anchors suitable for installation of electrical equipment (not furnished).

Figure 12: IPC2 Base Channels

After all equipment sections are properly joined together and the entire structure is bolted to the floor, install the incoming service conductors and load side cables.

Grounding and Bonding

NOTE: A system is “grounded” if it is grounded at any point ahead of the IPC2, whether the grounded conductor (neutral) is carried through to the loads, or not.

Service Equipment—Grounded System

For solidly *grounded* systems used as either service equipment or as a main IPC2 on a separately derived system:

Figure 13: Grounding Electrode Connector

1. Run a grounding electrode conductor from the grounding electrode at the installation site to the grounding electrode conductor connector (ground lug) located on the IPC2 ground bus (Figure 13). Select the material and size of this grounding electrode conductor to comply with Sections 250-62 and 250-66 of the NEC® or Sections 10-204 and 10-206 of the CEC, and install it as specified in Section 250-64 of the NEC or Section 10-908 of the CEC.
2. Install the main bonding jumper (provided with the IPC2) between the neutral assembly of the service entrance panelboard located in the IPC2 equipment and a ground lug located on the IPC2 unit ground bus. For torque values, refer to Table 3 on page 32.

   NOTE: If the IPC2 is fed from multiple sources (for example, double-ended systems), there may be two or more main bonding jumpers to install.

In Canada, a main bonding jumper cable is provided between the neutral assembly and ground bus. When disconnection of the bonding jumper is required (for example, for a Megger® test), remove the cable lug with cable from the neutral assembly. This is normally located near the line neutral lugs. Secure the cable and lug to maintain the required distance from phases and neutral.

NOTE: If the IPC2 is fed from multiple sources (for example, a double-ended system like a main-tie-main), there may be two or more main bonding jumpers installed.

Service Equipment—Ungrounded System

For *ungrounded* systems used as either service equipment, or as a main IPC2 on a separately derived system:

1. Run a grounding electrode conductor from the grounding electrode at the installation site to the grounding electrode conductor connector (ground lug) located on the IPC2 ground bus (Figure 13).
2. Select the material and size of this grounding electrode conductor to comply with Sections 250-62 and 250-66 of the NEC or Sections 10-700 and 10-702 of the CEC, and install it as specified in Section 250-64 of the NEC or Section 10-204 of the CEC.

Not Service Equipment

For either *grounded or ungrounded* systems, when an IPC2 is used neither as service equipment, nor as a main IPC2 on a separately derived system:

Use equipment grounding conductors sized according to Section 250-122 of the NEC or Section 10-206 of the CEC to connect the IPC2 frame and ground bus to the service ground.

High-Impedance Grounded Neutral Systems

For high-impedance grounded neutral systems:

Ground the system following the instructions provided with the system grounding equipment and in compliance with Section 250-36 of the NEC. Confirm that the IPC2 frame and ground bus are bonded in accordance with Section 250-102 of the NEC.

© 2005–2010 Schneider Electric All Rights Reserved

Conduit Area

1. Locate and terminate all conduit in the IPC2 enclosure in the “available conduit area” designated on the equipment drawing.
   a. When cables are entering the top of the IPC2, remove the IPC2 top plate and retain the hardware for reuse. For future reference, note that the top plates used on the 36-in. deep Transformer Combo structures include a rear-located notch.
   b. Add cutouts in the top plate as needed. Ensure no metal shavings are allowed to fall into the IPC2.
   c. Reinstall the top plate and secure it with the hardware retained in step a. For 36-in. deep Transformer Combo structures, ensure the top plate is installed with the notch located at the rear.
2. Install the conduit properly. Use hubs and ring connectors to protect the cables and prevent condensation on the conduit from entering the IPC2.

   NOTE: If top entry, do not use the top of the IPC2 to support the weight of the conduit. Support the conduit independently.

   Under seismic conditions, the top of the IPC2 can move as much as 3.00 in. (76 mm) in any direction. Any top incoming cables must accommodate this motion.
3. Bond all conduit, stubs, and ring connectors to the IPC2 enclosure with approved electrical connections.

IPC2 Top Plate Closing Plugs

A closing plug bag kit used to fill the four holes that result from the removal of the four top-located lifting eyebolts is provided with each structure. This kit is located inside the structure next to the front base channel. Install the closing plugs whenever the lifting eyebolts are removed. If additional plugs are needed, order kit number 80123-154-50 that includes four individual plugs.

Cable Pulling

IPC2 units are constructed to customer specifications for the cable entrance arrangement (for example, top or bottom feed). IPC2 components are arranged to give proper cable clearance and bending space for cables entering or exiting the IPC2 as specified on the equipment drawing.

Figure 14: General IPC2 Danger Label

1. Use only cable sizes suitable for a proper fit with the corresponding lugs.
2. Pull the proper number of line side and load side cables according to the load served and the NEC or CEC.
3. Position the cables inside the IPC2 so that they are not subject to physical damage.
4. Maintain the maximum possible bending radii and proper clearance to bus bars and grounded parts. If any cables are lying or bearing on structural members, support them to relieve this condition or place suitable protective material at the bearing point to protect the cable insulation.

   Additionally, when it is necessary to route feeder cables through the Transformer Combo transformer compartment, the installer must reliably route the cables as to ensure there is no direct contact between the cables and the transformer core or coils. **Do not** route cables directly over the transformer core or coils. Use of the cable support brackets on each side of the structure is recommended.

5. **Be certain to run all phase conductors, including the neutral, through the same opening where cables enter or leave the IPC2, or pass through any metal that has magnetic properties. Otherwise, overheating can result. See Section 300-20(a) of NEC.**
6. When instructed, brace or cable-lace the conductors.

Cable Terminations

Figure 15: Conductor Insulation Caution Label

1. Use a proper insulation stripping tool to strip a length of insulation from the end of the cable sufficient to fit into the full length of the lug barrel. Be careful not to nick or ring the strands.
2. Thoroughly clean aluminum cable contact surfaces with a wire brush, or scrub them with an abrasive cloth to remove oxides and foreign matter.
3. Immediately apply an acceptable joint compound to the bare aluminum surfaces.
4. If compression-type lugs are furnished, unbolt and remove them to create sufficient room for crimping the lugs to the cables with the crimping tool.
   a. Insert the cable into the lug barrel and, using the crimping tool, make the specified number of crimps per the manufacturer's recommendations.
   b. Wipe excess joint compound from the connector and insulation.
   c. With the cables connected, remount the lugs onto the bus bars or circuit breakers. Torque the bolts to the values given in "Section 9—Torque Values for Electrical Connections" on page 31.
5. Set screw-type lugs may be furnished as main incoming lugs and are standard on molded case circuit breakers. Torque these lugs **to, but do not exceed**, the specified values. Torque values for circuit breaker lugs are marked on these units. Torque values for other IPC2 lugs are marked on the IPC2.

Ground-Fault Protection for Equipment

⚠ WARNING

LOSS OF EQUIPMENT
GROUND-FAULT PROTECTION

Do not connect grounding conductors to any load neutral terminal(s).

Failure to follow these instructions can result in death or serious injury.

According to Section 230-95(c) of the NEC, "The ground-fault protection system shall be performance tested when first installed . . . . A written record of this test shall be made and shall be available to the authority having jurisdiction."

Schneider Electric tests the factory-installed ground-fault system prior to shipment. However, improper grounding of the IPC2 and devices downstream at the job site will defeat the ground-fault system. Performance testing of the ground-fault system, as stated in the NEC, requires injecting sufficient current into the system to test the ground fault. High current injection by a certified testing organization will test the polarity of the ground-fault sensors, interconnection wiring, and proper bonding of the neutral.

NOTE: Some equipment ground-fault systems require field connections at the job site. Consult the IPC2 interconnection wiring drawing for details.

Section 5—Pre-Energizing Checkout Procedure

Conduct a complete inspection **before** the IPC2™ is energized to ensure that all components function and operate properly. **Complete every step of the checkout procedure listed before energizing the IPC2.**

1. Check the ground bus bar connections. Torque values are listed in Table 3 on page 32.
2. Check all accessible connections for tightness.
3. Check all factory- and field-installed lug terminations for tightness.
4. Check the IPC2 enclosure for dents or other damage that reduces electrical clearances inside the IPC2.
5. Remove all foam blocks, or other temporary cushioning or retaining material, from the electrical devices.
6. Manually open and close all switches, circuit breakers, and other operating mechanisms, checking for correct alignment and free operation.
7. Operate all electrically operated switches, circuit breakers, and other devices equipped with remote operators (not under load). An auxiliary source of control power may be necessary to accomplish this.
8. Check all relays, meters, and instrumentation to verify that all field-installed wiring connections are made properly and that the devices function properly.
9. Current transformers (CTs) supplied for customer use require connection to a metering device load before energizing. Verify that the metering device load is properly connected, including main IPC2 connections to remote equipment.
10. All CT circuits supplied by Schneider Electric for customer metering use are shorted for shipment. Remove shorting terminal screws on shorting terminal blocks or jumpers and store in the block.
11. Factory-installed molded case circuit breakers, 250 A frames or larger, may have an adjustable magnetic trip, which is shipped on the “LO” setting. The markings between “LO” and “HI” settings represent a range of instantaneous magnetic trip values of 5–10 times the circuit breaker’s continuous current rating. To provide coordinated operation during a fault, adjust the magnetic trip as outlined in the respective instruction bulletin. All poles are adjusted simultaneously, using a screwdriver, by the single setting (Figure 16).
12. On IPC2 units containing an electronic trip circuit breaker, set the tripping characteristic curve of the adjustable electronic trip unit per the job requirements, or as outlined in the respective instruction bulletin.
13. If ground-fault protection is furnished on molded case circuit breakers, refer to “Section 11—Reference Publications” on page 34 for information to obtain circuit breaker publications.
14. Inspect all cables to ensure the insulation has not been damaged in any fashion.
15. Verify that all grounding connections are correctly made. If the IPC2 is used as a service entrance, double check to see that the main bonding jumper is connected.

Figure 16: Instantaneous Trip Setting

CAUTION

HAZARD OF EQUIPMENT DAMAGE

Do not pry open or spread the fuse mounting clips. This can cause a loose connection, resulting in overheating.

Failure to follow these instructions can result in equipment damage.

© 2005–2010 Schneider Electric All Rights Reserved

16. Conduct an electrical insulation resistance (Megger®) test to ensure that the IPC2 is free from short circuits and undesirable grounds.
    a. Open all control power and metering disconnects or remove the fuses from the control circuits.
    b. Disconnect the neutral connection at any TVSS or other electronic device prior to performing the electrical insulation resistance test; reconnect to the device after the test.
    c. With the neutral isolated from the ground and the power switches and circuit breakers open, conduct electrical insulation tests from phase-to-phase, phase-to-ground, phase-to-neutral, and neutral-to-ground. If the resistance reads less than one megohm while testing with the branch circuit breaker devices in the open position, the system may be unsafe and should be investigated. Consult Square D Services at 1-888-778-2733 (US) or 1-800-265-3374 (Canada) to help correct any problems.
17. Record resistance values. See “Section 10—IPC2™ Power Center Insulation Resistance Chart” on page 33.
18. After completing the electrical insulation resistance test, replace all control power fuses that may have been removed, and close power disconnects that have been opened.
19. Check all field-installed wiring. Make certain it is clear of all live parts, and when instructed, secured to withstand fault currents.

    NOTE: MG-, MJ-, P-, and R-frame circuit breakers require cable lacing within the IPC2 unit. Follow lacing instructions provided with these circuit breakers.
20. Verify that all control wiring between sections is connected.
21. Vacuum to remove any dust, scrap wire, or other debris.
22. Replace all covers; check for any pinched wires, and close doors. Make certain all enclosure parts are aligned properly and securely fastened.

⚠ CAUTION

HAZARD OF EQUIPMENT DAMAGE OR INJURY

- Remove the long-time rating plug before electrical insulation testing a circuit breaker that has a label stating “Warning: Disconnect Plug Before Dielectric Test.”
- Some Micrologic® trip units are not rated for voltages that would occur during electrical resistance insulation testing.
- Open all control and metering disconnects from the control circuits.

Failure to follow these instructions can result in injury or equipment damage.

CAUTION

HAZARD OF EQUIPMENT DAMAGE

Do not use an air hose to blow out the IPC2. The dust may settle inside relays and overcurrent devices, causing overheating and improper operation.

Failure to follow these instructions can result in equipment damage.

Section 6—Energizing the IPC2™

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Correct short-circuit conditions detected during the checkout procedures described in “Section 5—Pre-Energizing Checkout Procedure”, beginning on page 24.
- Qualified electrical personnel must be present when energizing this equipment for the first time.
- Follow the instructions in this section to properly energize the IPC2.

Failure to follow these instructions will result in death or serious injury.

1. No load should be on the IPC2 when it is energized. Turn off all downstream loads.
2. Energize the IPC2 in the following sequence:
   a. Turn on all control power disconnects before energizing the IPC2. Refer to the record drawings supplied with equipment to see if control power disconnects are supplied.
   b. Close any open doors and/or covers.
   c. Close the main device(s).
   d. Close each branch circuit breaker or branch fusible switch.
   e. Proceed to each panelboard and other downstream load.
3. After all overcurrent protective devices are closed, turn on all loads (e.g., lighting circuits, contactors, heaters, and motors).

Section 7—Maintaining the IPC2™

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- Always practice lock-out/tag-out procedures according to OSHA requirements.
- Inspect and perform preventive maintenance only on IPC2 equipment to which power has been turned to the OFF position, disconnected, and electrically isolated (unless otherwise specified) so that no accidental contact can be made with energized parts.

Failure to follow these instructions will result in death or serious injury.

Periodic maintenance of the IPC2 includes cleaning, lubrication, and exercising component parts. The interval between maintenance checks can vary depending upon the amount of usage and environmental conditions of each installation. The maximum recommended inspection interval is one year. This definition for periodic maintenance applies throughout this bulletin, unless otherwise noted.

Always inspect the IPC2 after a fault. (Refer to “Section 8—Adverse Circumstances”, beginning on page 30.) Service bulletins for the various disconnecting and overcurrent devices mounted in the IPC2 are available through your local Schneider Electric field office.

General Inspection and Cleaning

The following danger label is applied to the IPC2 only when a breaker is installed in the bottom compartment of a transformer combo section.

Figure 17: Breaker in Bottom Compartment of Transformer Combo Section Danger Label

The following danger label is applied to the IPC2 at a control panel location.

Figure 18: Control Panel Danger Label

1. Turn off all power supplying this equipment before working on or inside equipment.
2. If equipped with a breaker in the transformer section, identify the use of this breaker before working on or inside this equipment.
3. Always practice lock-out/tag-out procedures according to OSHA requirements.
4. Always use a properly rated voltage sensing device to confirm all power is off.
5. Vacuum the IPC2 interior to remove any dirt or dust deposits. Wipe all bus bars, insulators, cables, etc., with a clean, dry, lint-free cloth.
6. Check the IPC2 interior carefully for moisture, condensation build-up, or signs of any previous wetness. Moisture can cause insulation failures and rapid oxidation of current-carrying parts. Inspect all conduit entrances and cracks between the enclosure panels for dripping leaks. Condensation in conduits may be a source of moisture and must not be allowed to drip onto live parts or insulating material. Take the necessary steps to eliminate the moisture and seal off all leaks.
7. Inspect the IPC2 for any signs of overheating. Discoloration, flaking, and cracking of insulation or metal parts are indications of overheating.

   Inspection of the cable insulation within the Transformer Combo transformer compartment is imperative.

   NOTE: If overheating occurs, be sure that all conditions that caused the overheating have been corrected. Loose or contaminated connections can cause overheating.
8. Check for signs of rodent nesting in the IPC2. If required, use a good exterminating technique in the general area of the IPC2.

   NOTE: Do not place or use exterminating substances and chemicals inside the IPC2. Some of these products attract rodents.
9. Carefully inspect all devices for any visibly worn-out, cracked, or missing parts.
10. Manually open and close switches and circuit breakers several times to verify they are working properly.
11. Verify that all locking mechanisms are working properly.

CAUTION

HAZARD OF EQUIPMENT DAMAGE

- Do not use an air hose to blow out the IPC2. The dust may settle inside relays and overcurrent devices, causing overheating and improper operation.
- Do not allow paint, chemicals, or petroleum-based solvents to contact plastics or insulating materials.

Failure to follow these instructions can result in equipment damage.

Panel Bus Bar Joints, Lug Terminations, and Insulating Materials

CAUTION

HAZARD OF EQUIPMENT DAMAGE

- Do not sand or remove plating on any bus bar, splice bar, or terminal lug.
- Damage to plating can result in overheating. Replace damaged part. Contact Square D Services at 1-888-778-2733 (US) or 1-800-265-3374 (Canada).

Failure to follow these instructions can result in equipment damage.

1. Do not retighten panel bus bar joints after the pre-energizing checkout procedure is complete.
2. Check all panel bus bar joints and terminal lugs for any pitting, corrosion, or discoloration resulting from high temperatures or subjection to high fault conditions. If any damage has occurred, contact Square D Services in the US at 1-888-Square D (1-888-778-2733) or in Canada at 1-800-265-3374 to help correct any problems. If cleaning is required, use Lectra-Clean®, made by CRC Industries, Inc.
3. Inspect all insulating materials. Before re-energizing the IPC2, replace insulators with any visible damage (such as cracks).

General Lubrication Information

For field maintenance re-lubrication of bus/plug-on connections, use Schneider Electric catalog number PJC7201 (Electric Joint Compound).

Automatic Transfer Switches

Consult the manufacturer's bulletin about these devices for all installation, operation, and maintenance instructions.

Circuit Breakers

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- If circuit breaker settings are adjusted, do not set the long time trip rating at a higher ampacity than the rating of the bus bar or load cables it supplies; overheating can occur.
- Before energizing the IPC2, all unused circuit breaker mounting spaces must be filled with blank fillers and/or extensions as listed in Table 1.

Failure to follow these instructions will result in death or serious injury.

Schneider Electric circuit breakers are designed and manufactured as totally sealed units requiring minimal periodic maintenance.

Exercise circuit breakers at least once a year to ensure proper operation. For general maintenance:

1. Trip the circuit breaker by pushing the Push-To-Trip or "Open" button located on the face of the circuit breaker. Refer to the appropriate circuit breaker bulletin for the specific location of this button.
2. Manually open and close the circuit breaker two to three times.

   NOTE: Schneider Electric bulletin 0600DB9901 "Field Testing and Maintenance Guide for Micrologic® Electronic Trip and Thermal-magnetic Molded Case Circuit Breakers" provides more in-depth information. Refer to "Section 11—Reference Publications" on page 34 and contact your local Schneider Electric field office to obtain this bulletin.

   Refer to individual circuit breaker instruction bulletins shipped with the IPC2 for additional maintenance information, such as changing rating columns or adjustable settings and removing circuit breakers. If the instruction bulletins are not available, see "Section 11—Reference Publications" on page 34, and contact your local Schneider Electric field office for information to obtain the appropriate bulletins.

© 2005–2010 Schneider Electric All Rights Reserved

CAUTION

HAZARD OF EQUIPMENT DAMAGE

- Do not remove the protective lubricant on the plug-on connectors.
- If additional lubrication is required, apply a coating of electrical joint compound, catalog number PJC7201, to the plug-on connector's contact surfaces.

Failure to follow these instructions can result in equipment damage.

3. The universal test set, Schneider Electric catalog number UTS3, is available to test all Schneider Electric circuit breakers equipped with Micrologic® trip units. It runs trip unit tests automatically, with prompts to the user for initial information. Test modules for each circuit breaker frame are used to store data necessary for automatic tests. Series B Micrologic trip units require test module CBTMB, which is included in UTS3.

   Masterpact® and Powerpact® circuit breakers with Micrologic trip units require the full-function test set (catalog no. 533595) or hand-held test set (catalog no. 533594).

   NOTE: Tests may be conducted with a circuit breaker installed in the IPC2; removing the circuit breaker is not required. The IPC2 must be de-energized.

Ground-Fault Protection for Equipment

Check the terminal connections on the equipment ground-fault protection system at least once a year for tightness and corrosion. If the system can be tested with or without tripping the main or branch device, directions for testing the system are in the device bulletin. Otherwise, testing the equipment ground-fault protection system will trip the main or branch device to which it is connected. If the equipment ground-fault sensor or relay is physically or electrically damaged, replace it.

If the ground-fault protection system does not operate properly and additional equipment has been connected to the installation since the last maintenance test/check, de-energize the entire system and check for grounds on the neutral downstream from the main bonding jumper. If no downstream grounds are detected and the equipment ground-fault system is not operating properly, contact Square D Services in the US at 1-888-Square D (1-888-778-2733) or in Canada at 1-800-265-3374.

Refer to Schneider Electric bulletin 0600DB9901 *"Field Testing and Maintenance Guide for Micrologic® Electronic Trip and Thermal-magnetic Molded Case Circuit Breakers"* for additional testing information. If the bulletin is not available, refer to "Section 11—Reference Publications" on page 34 and contact your local Schneider Electric field office to obtain the bulletin.

Section 8—Adverse Circumstances

This section includes, but is not limited to, all electrical components of the IPC2™.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- Turn off all power supplying this equipment before working on or inside the equipment.
- Always use a properly rated voltage sensing device to confirm all power is off.
- Before energizing the IPC2, all unused circuit breaker mounting spaces must be filled.

Failure to follow these instructions will result in death or serious injury.

NOTE: Before attempting to re-energize the IPC2 following an adverse circumstance, contact Square D Services in the US at 1-888-Square D (1-888-778-2733) or in Canada at 1-800-265-3374, for special instructions.

Inspection Following a Short Circuit

High mechanical and thermal stresses developed by short circuit currents may damage conductors and insulation. If a short circuit occurs, make a thorough inspection of the entire system and verify that no damage to conductors or insulation has occurred. Check the overcurrent protection device that interrupted the short circuit current for possible arcing damage.

Do not open sealed devices, such as molded case circuit breakers. These devices should be replaced if damaged. Before energizing the IPC2, all unused circuit breaker mounting spaces must be filled. For more information about these devices and to obtain the appropriate bulletin, refer to “Section 11—Reference Publications” on page 34.

Clean-up Following a Short Circuit

The insulating properties of some organic insulating materials may deteriorate during an electrical arc. If so:

1. Remove any soot or debris.
2. Replace carbon-tracked insulation.

Water-Soaked Equipment

Do not clean or repair an IPC2 that has been exposed to large volumes of water or submerged at any time. Current-carrying parts, insulation systems, and electrical components may be damaged beyond repair. Do not energize the IPC2. Contact Square D Services, and also refer to Square D Data Bulletin 0110DB0401R9/05.

Water-Sprayed or Splashed Equipment (Clean Water Only)

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- Turn off all power supplying this equipment before working on or inside the equipment.
- Always use a properly rated voltage sensing device to confirm all power is off.

Failure to follow these instructions will result in death or serious injury.

© 2005–2010 Schneider Electric All Rights Reserved

If the IPC2 has been sprayed or splashed with small amounts of clean water, make a thorough inspection of the entire system and verify that no damage to conductors or insulation has occurred. Do not open sealed devices such as molded case circuit breakers or fuses. These devices should be replaced if damaged. For more information about these devices and to obtain the appropriate instruction bulletin, refer to “Section 11—Reference Publications” on page 34.

Inspection and Clean-up of Clean Water Sprayed or Splashed Equipment

⚠ CAUTION

HAZARD OF EQUIPMENT DAMAGE OR INJURY

- Remove the long-time rating plug before electrical insulation testing a circuit breaker that has a label stating “Warning: Disconnect Plug Before Dielectric Test.”
- Some Micrologic trip units are not rated for voltages that would occur during electrical resistance insulation testing.
- Open all control and metering disconnects from the control circuits.

Failure to follow these instructions can result in injury or equipment damage.

Follow the steps below only if:

- No signs of physical damage to the equipment are present.
- The IPC2 has not been submerged or exposed to water for long periods of time.
- The water that has been in contact with the IPC2 has not been contaminated with sewage, chemicals, or other substances that can negatively affect the integrity of the electrical equipment.
- The water that has been in contact with the IPC2 has not entered any area of the enclosure that may contain wiring located above any live part. Specifically, inspect for water entering through conduits located above live parts.

If any of these conditions have not been met, contact Square D Services in the US at 1-888-Square D (1-888-778-2733) or in Canada at 1-800-265-3374.

1. Turn off all power supplying this equipment before working on or inside the equipment.
2. Always use a properly rated voltage sensing device to confirm all power is off.
3. Disconnect and electrically isolate the IPC2 so no contact can be made with energized parts.
4. Wipe off all moisture from the panel bus, insulators, and insulating material with a clean, dry, lint-free cloth. Do not use cleaning agents or water displacement sprays.
5. Prepare the IPC2 for insulation resistance (Megger®) testing by disconnecting all line-side supply connections and all load-side cable connections to isolate the IPC2 from the wiring system.
6. Turn all circuit breakers or switches to the ON position. The IPC2 must remain completely de-energized.
7. Use a megohmmeter with a capacity of 500–1000 Vdc, and apply voltage from:
   a. each phase-to-ground with circuit breaker on
   b. phase-to-phase with circuit breaker on
8. Record resistance values. See “Section 10—IPC2™ Power Center Insulation Resistance Chart” on page 33.
9. If resistance measurements are less than 1.0 megohm, call Square D Services for recommendations.
10. If resistance measurements are greater than 1.0 megohm, the equipment can be energized using the procedures listed in “Section 6—Energizing the IPC2™” on page 26.

Integrated Power Center 2 (IPC2™) Application Guide
Class 2230

Retain for future use.

Introduction

Square D® Integrated Power and Control Solutions (IPaCS) integrates electrical distribution and controls in a factory assembled and pre-wired solution. Designed with the flexibility to meet individual customer requirements, Integrated Power Center 2 (IPC2™) enclosures are available with NQ®, NF, and I-Line® panelboard interiors and distribution dry transformers.

Optional distribution and control equipment include Powerlink® lighting control, contactors, PowerLogic monitoring and metering, automatic transfer switches, and transient voltage surge suppressors (TVSS). IPC2 solutions can be further customized to include third party components such as building management systems.

All IPC2 sections are available in Type 1, Type 1 with driphood, or Type 3R enclosures. IPC2 equipment is listed to UL891.

The 42-circuit limitation for Lighting and Appliance Panelboards has been removed from Article 408 of the 2008 National Electrical Code® (NEC®) edition. If the 2008 NEC edition has not been adopted for use in your area, you are still required to adhere to the 42-circuit rule for Lighting and Appliance panelboards.

IPC2: Transformer Combo

The Transformer Combo integrates panelboards, individually mounted circuit breakers or lighting contactors with a dry type transformer into one factory-assembled and pre-wired solution.

All configurations have factory-installed Type THHN copper cable.

Hazard Categories and Special Symbols

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates an imminently hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a potentially hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a potentially hazardous situation which, if not avoided, **can result in** minor or moderate injury.

NOTICE

NOTICE is used to address practices not related to physical injury. The safety alert symbol is not used with this signal word.

NOTE: Provides additional information to clarify or simplify a procedure.

Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

Introduction

This bulletin contains instructions for installing Square D™ brand I-Line™ circuit breaker panelboards. These panelboards are Underwriters Laboratories (cULus) listed and accept I-Line branch circuit breakers.

For technical support on the installation of this panelboard, contact the Schneider Electric at customer support 1-888-778-2733.

See the labels on the equipment for rating and safety information. Additional equipment labels are provided with this document.

Safety Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside the equipment.
- Always use a properly-rated voltage sensing device to confirm all power is off.
- Read and understand this entire instruction bulletin and the latest edition of the NEMA PB 1.1 standards publication included before installing, operating, or maintaining this equipment.
- Local codes vary, but are adopted and enforced to promote safe electrical installations. A permit may be needed to do electrical work, and some codes may require an inspection of the electrical work.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Installation

This section provides instructions for the following I-Line panelboard procedures:

- Interior Mounting into Square D Brand Enclosures, on page 9
- Neutral Bonding Strap Installation, on page 12
- I-Line Circuit Breaker Installation and Removal, on page 14
- Interior Trim Barrier Preparation, on page 18

Interior Mounting into Square D Brand Enclosures

A separate standards publication, titled “General Instructions for Proper Installation, Operation, and Maintenance of Panelboards Rated 600 Volts or Less” (NEMA PB1.1-2007), has been provided with this equipment. Familiarize yourself with the content of this document before proceeding with any of the following procedures.

If you did not receive a copy of this document, or if you have any questions regarding this equipment, contact your local distributor or Schneider Electric representative.

NOTICE

HAZARD OF EXCESSIVE HEAT DUE TO LOOSE CONNECTION

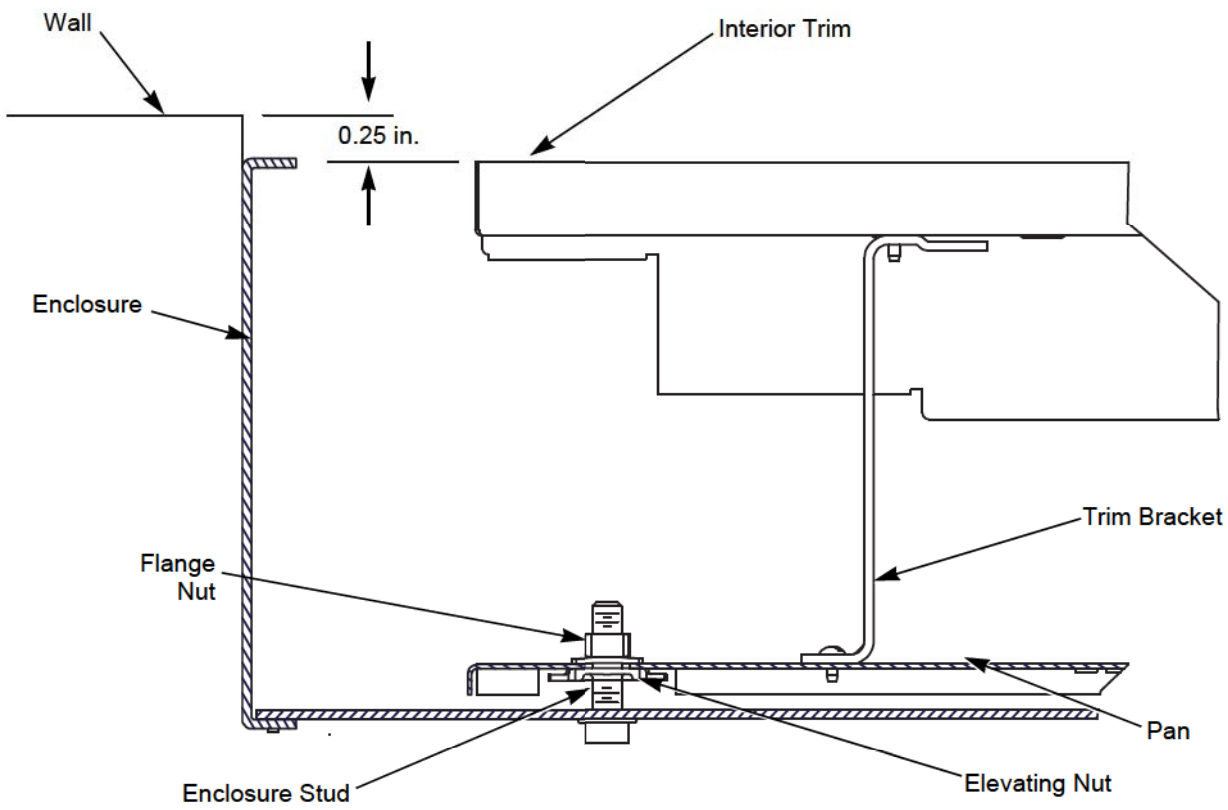
- Ensure all connections are properly tightened.
- Refer to the torque information label provided on the panelboard before tightening the connections.

Failure to follow these instructions can result in equipment damage.

To properly mount and install the I-Line panelboard enclosure, please refer to the NEMA PB 1.1-2007 standards publication, and follow the instructions below for either “Surface Mounting (Enclosure Mounted on Wall)” or “Flush Mounting (Enclosure Recessed in Wall).”

ENGLISH

Surface Mounting (Enclosure Mounted on Wall)



1. Mount the enclosure as instructed in the NEMA PB 1.1 standards publication.
2. Install one elevating nut on each enclosure stud.
3. Remove the interior trim from the trim brackets.
4. Install the interior as described below:
   a. Set the interior on the enclosure studs and secure with flange nuts (see Figure 1). Screwdriver blade may be inserted in elevating nut slot to facilitate adjustment.
   b. Adjust each elevating nut to maintain a maximum distance of 0.125 in. between the interior trim and the front/door assembly.
   c. Tighten the flange nuts against the pan.
   d. Remount the interior trim after wiring.
5. If used as service entrance equipment, neutral bonding is required (see “Neutral Bonding Strap Installation” on page 12).
6. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.

Flush Mounting (Enclosure Recessed in Wall)

1. Mount the enclosure as instructed in the NEMA PB 1.1-2007 standards publication.
2. Install one elevating nut on each enclosure stud.
3. Remove the interior trim from the trim brackets.
4. Install the interior as described below:
   a. Set the interior on the enclosure studs and secure with flange nuts (see Figure 1 on page 10). Screwdriver blade may be inserted in elevating nut slot to facilitate adjustment.
   b. Adjust each elevating nut to position the lip of the interior trim approximately 0.25 in. from the outside wall line.
   c. Tighten the flange nuts against the pan.
   d. Remount the interior trim after wiring.
5. If used as service entrance equipment, neutral bonding is required. See the “Neutral Bonding Strap Installation” instructions on page 12.
6. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.

Neutral Bonding Strap Installation

The neutral bonding strap should be used only when the panelboard is **installed** as service equipment.

To properly bond the neutral to the panelboard, follow the instructions for either “Standard Neutral Bonding Strap Installation” or “Neutral with Current Transformer Bonding Strap Installation” on pages 13 and 14, respectively.

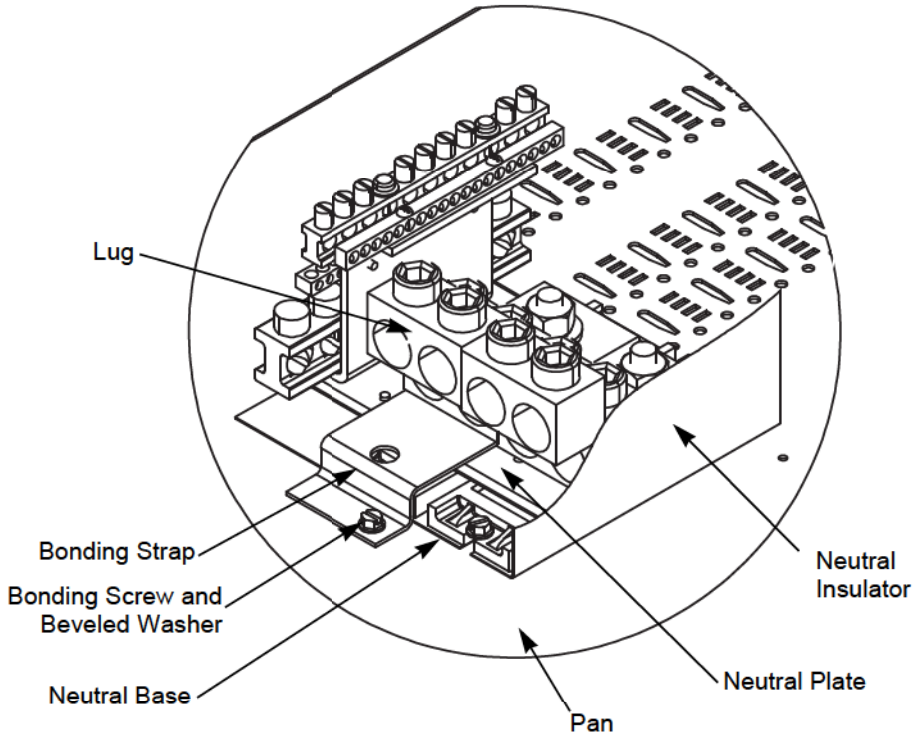
⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- Turn off all power supplying this equipment before working on or inside the equipment.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Always use a properly-rated voltage sensing device to confirm all power is off.
- The main bonding strap should be used only when the panelboard is installed as service equipment.
- Do not mix the mounting screws with the interior trim screws.

Failure to follow these instructions will result in death or serious injury.

NOTE: The bonding strap parts are found in the bag assembly provided with the interior.



ENGLISH

Standard Neutral Bonding Strap Installation

To install a neutral bonding strap on an I-Line panelboard, refer to Figure 2 and follow the instructions below.

1. Remove lug. Retain lug and fastening hardware.
2. Place bonding strap between neutral plate and lug, as shown.
3. Secure bonding strap to pan with bonding screw and beveled washer. Tighten the bonding screw to 65–75 lb-in (7.3–8.5 N•m).
4. Reinstall lug with the hardware retained in step 1. Tighten to 60–70 lb-in (6.8–7.9 N•m).

Figure 2: Standard Neutral Bonding Strap Installation

ENGLISH

Neutral with Current Transformer Bonding Strap Installation

To install a neutral bonding strap on an I-Line panelboard with a current transformer, refer to Current Transformer Neutral Bonding Installation Instructions, Schneider Electric document 80043-706-xx or 80043-789-xx, that is supplied with the current transformer neutral.

I-Line Circuit Breaker Installation and Removal

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly-rated voltage sensing device to confirm that all power is off.
- All unused spaces must be filled with blank fillers.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

I-Line Circuit Breaker Installation

Refer to Figure 3 on page 16 for the following instructions:

1. Turn off all power to the panelboard.
2. Remove the interior trim barrier.
3. Turn the circuit breaker off. Position the circuit breaker jaws against the bus bar stack so the guiding boss on the bottom of the circuit breaker is oriented towards the alignment groove in the bus insulator base, and the “fingers” of the circuit breaker mounting bracket fit into the keyslots in the pan.

   NOTE: Install the main circuit breaker adjacent to the main lugs.
4. Place a screwdriver through the rectangular hole in the circuit breaker mounting bracket and into the screwdriver slot in the mounting pan. Ratchet the circuit breaker firmly into the bus bar stack and align the retaining screw with the 0.219 in. (5.6 mm) mounting hole in the pan.
5. Tighten the retaining screw securely to prevent the circuit breaker from moving.

   NOTE: Ensure the retaining screw is tight, but do not tighten it enough to bend the mounting bracket.
6. **For main circuit breakers only:**
   Attach the “Main Breaker” label to the circuit breaker cover.
7. Reinstall the interior trim barrier.
8. Re-energize the panelboard.
9. Turn the circuit breaker on.

NOTE: I-Line circuit breakers are supplied with factory-applied joint compound on the plug-on connectors. The compound must not be removed because it contributes to the overall performance of the connection.

Whenever an I-Line circuit breaker is removed and reinstalled, the joint compound must be reapplied. A two-ounce container of compound especially formulated for I-Line plug-on connectors is available for purchase (catalog number PJC-7201).

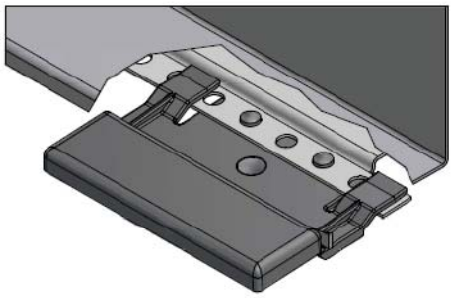
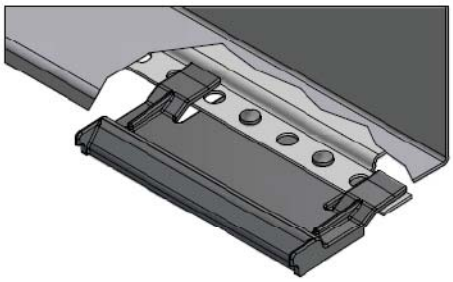
Figure 3: I-Line Circuit Breaker Installation and Removal



I-Line Circuit Breaker Removal

Refer to Figure 3 for the following instructions:



1. Turn off all power to the panelboard.
2. Turn the circuit breaker off.
3. Remove the interior trim barrier.
4. Loosen the retaining screw(s) in the circuit breaker mounting bracket until the screw(s) is completely removed from the 7/32 in. (5.6 mm) mounting hole in the mounting pan.
5. Place the screwdriver through the rectangular hole in the circuit breaker mounting bracket and into the screwdriver slot in the mounting pan. Ratchet the circuit breaker away from the bus bar stack.
6. Lift the circuit breaker away from the bus bars.
7. Install the blank fillers where the circuit breaker was removed, using Table 1 on page 18 as reference.
8. Secure the blank filler extensions to the interior trim barrier (HCPSU, HCP, and HCRU panelboards only), using Table 1 on page 18 for reference. Mount the extension over the mounting bracket in the deadfront as shown in Figure 4 on page 17.

9. Reinstall the interior trim barrier.
10. Re-energize the panelboard.

Circuit Breaker Reset Instructions

If the circuit breaker is tripped, the handle will be at the mid-position between ON and OFF. To reset the circuit breaker, push the handle to the OFF position, then to the ON position.

Interior Trim Barrier Preparation

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Before energizing the panelboard, all unused spaces must be filled with blank fillers.
- Replace all devices, doors, and covers before energizing this equipment.

Failure to follow these instructions will result in death or serious injury.

NOTICE

RISK OF IMPROPER ASSEMBLY

- Do not disassemble the I-Line Bus Stack Assembly.
- If maintenance is required, contact Schneider Electric.

Failure to follow these instructions can result in severe equipment damage and will void the warranty.

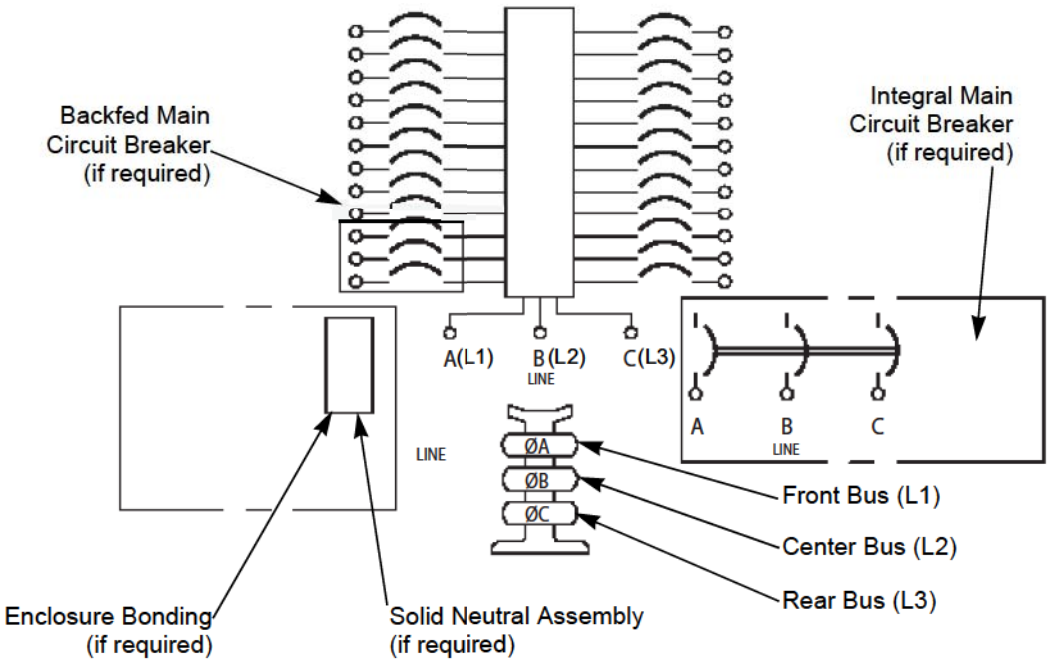
1 Additional information is provided on the panelboard. See the main circuit breaker rating, if used.

2 Unless otherwise specified.

3 Requires use of solid neutral assembly. See panelboard.



4 For grounded “B” phase system.

5 For use in Canada only.

6 When wiring for delta systems, phases “A” and “C” must be 120 V to neutral, with phase “B” 208 V to neutral. Connect only circuit breakers rated 240 V AC minimum, not 120 V or 120/240 V to “B” phase.

ENGLISH

Figure 6: Main Lugs / Main Circuit Breaker Wiring Diagram

NOTE: For 1Ø systems, the center bus is not used.

NOTE: Branch connections phasing is determined by the circuit breaker selected. See the latest catalog or the Digest for circuit breaker selection.

NOTE: Assure that the circuit breaker voltage rating is appropriate for the system. With the selection of proper units, any of the listed voltage systems can be used.

Panelboard Ratings

Refer to NEC section 110-22, 2011 Edition and CEC rule 12-014, 2002 Edition for more information. The series rated system label is located in the bag assembly. Short circuit tests are conducted at 100–105% of the maximum panelboard voltage. Interiors with CE mark meet IEC 61439-1 and IEC 61439-2.

Additional Short Circuit Current Ratings

Square D I-Line plug-on lugs installed in this panelboard and protected by indicated Square D circuit breakers are suitable for use where the available short circuit current is not greater than that shown in the following table. The short circuit current rating cannot exceed the rating marked on the protecting circuit breaker. The protecting circuit breakers may be the main, or if plugged onto the same I-Line bus stack, may be downstream from the plug-on lugs.

CE Marking

Interiors with the "CE" mark meet the IEC 61439-1 and IEC 61439-2 standards. Main Lug interiors with the "CE" mark have been tested to withstand 42,000 RMS symmetrical amperes for 30 cycles. Only IEC rated circuit breakers may be used with "CE" marked interiors and the short circuit rating of the interior is limited to the lowest IEC rated branch breaker unless series rated with an IEC rated main breaker in Table 4. (See Digest for details)

1 Always ensure compression lugs are installed in panelboards that will provide wire bending space in accordance with NEC Article 312.6, 2011 Edition.

2 Unless otherwise specified, wire sizes apply to both aluminum and copper conductors.

3 Use crimp tools in accordance with instructions that are provided within each lug kit.

1 Always ensure compression lugs are installed in panelboards that will provide wire bending space in accordance with NEC Article 312.6, 2011 Edition.

2 Unless otherwise specified, wire sizes apply to both aluminum and copper conductors.

3 When this lug is installed on a vertically mounted main circuit breaker, in an HCP interior, add box extension HC-4212-DEX (F or S) to the end of that enclosure.

4 Use crimp tools in accordance with instructions that are provided within each lug kit.

5 Always ensure compression lugs are installed in panelboards that will provide wire bending space in accordance with NEC Article 312.6, 2011 Edition. I-LINE panelboards with a Type 1 enclosure require a 5.0 in. extended width box when the branch breakers use these lugs (these compression lugs may not be used in weatherproof enclosures). Contact your local Schneider Electric representative for assistance.

6 This lug is only allowed in HCP/HCPSU panelboards with Type 1 enclosures with a 5.0 in. wide side extension.

7 For L-frame circuit breakers only.

HAZARD CATEGORIES AND SPECIAL SYMBOLS

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to potential personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates an imminently hazardous situation which, if not avoided, will result in death or serious injury.

⚠ WARNING

WARNING indicates a potentially hazardous situation which, if not avoided, can result in death or serious injury.

⚠ CAUTION

CAUTION indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

CAUTION

CAUTION, used without the safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property damage.

Provides additional information to clarify or simplify a procedure.

PLEASE NOTE

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

Introduction

This bulletin contains instructions for installing Square D® brand NF and NFOM circuit breaker panelboards. These panelboards are Underwriters Laboratories (cULus) listed and accept ECB, EDB, EGB, and EJB branch circuit breakers.

For technical support on the installation of this panelboard, contact the Square D/Schneider Electric Customer Information Center at 1-888-SquareD (1-888-778-2733).

See the labels on the equipment for rating and safety information. Additional equipment labels are provided with this document.

Safety Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Read and understand this entire instruction bulletin and the included NEMA PB 1.1 standards publication before installing, operating, or maintaining this equipment.
- Local codes vary, but are adopted and enforced to promote safe electrical installations. A permit may be needed to do electrical work, and some codes may require an inspection of the electrical work.
- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside the equipment.
- Always use a properly-rated voltage sensing device to confirm all power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Installation

This section provides instructions for the following NF/NFOM panelboard procedures:

- “Interior Mounting for Square D Brand Enclosures” on page 8
- “Neutral Bonding Strap Installation” on page 11
- “ECB, EDB, EGB, and EJB Circuit Breaker Installation and Removal” on page 15
- “Circuit Breaker Reset Instructions” on page 17
- “Interior Trim Preparation” on page 18

Interior Mounting for Square D Brand Enclosures

A separate standards publication, titled “General Instructions for Proper Installation, Operation, and Maintenance of Panelboards Rated 600 Volts or Less” (NEMA PB1.1), has been provided with this equipment. Familiarize yourself with the content of this document before proceeding with any of the following procedures.

If you did not receive a copy of this document, or if you have any questions regarding this equipment, contact your local distributor or Schneider Electric representative.

CAUTION

HAZARD OF EQUIPMENT DAMAGE

- Ensure all connections are properly tightened.
- Refer to the torque information label provided on the panelboard before tightening the connections.

Failure to follow these instructions can result in equipment damage.

To properly mount and install the NF/NFOM panelboard interior, please refer to the NEMA PB 1.1 standards publication, and follow the instructions below for either “Surface Mounting (Enclosure Mounted on Wall)” or “Flush Mounting (Enclosure Recessed in Wall).”

ENGLISH

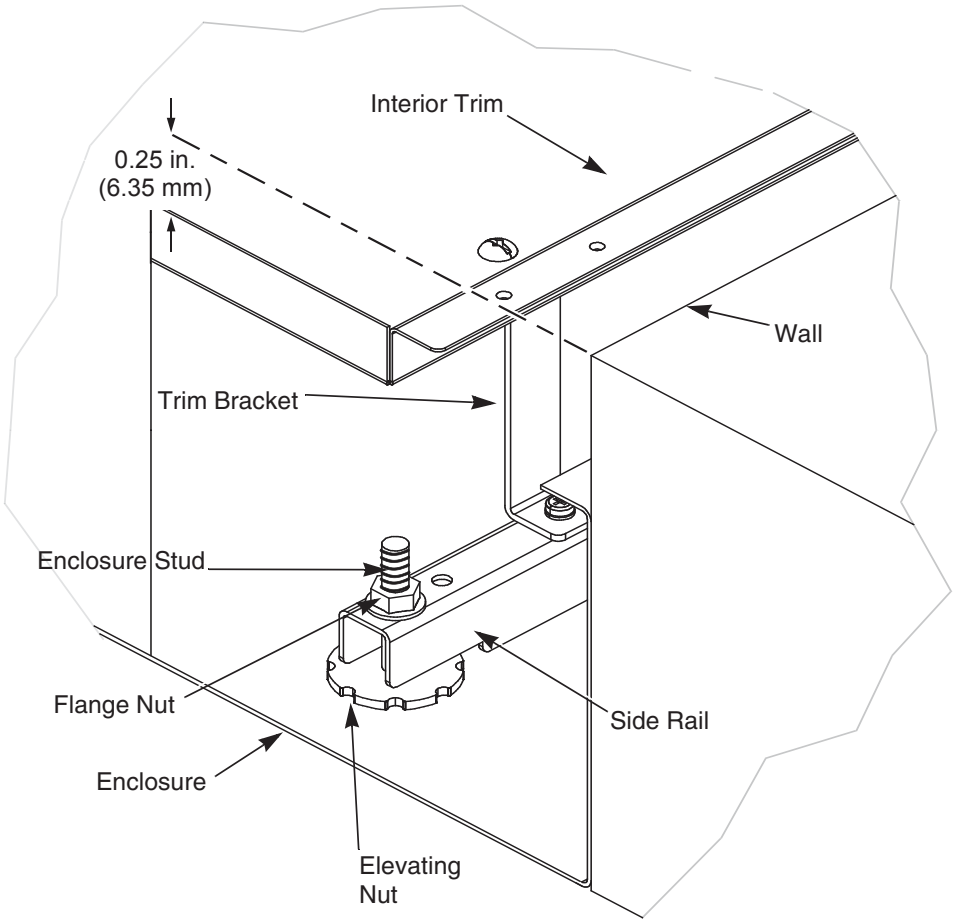
Surface Mounting (Enclosure Mounted on Wall)

1. Mount the enclosure as instructed in the NEMA PB 1.1 standards publication.
2. Remove the interior trim from the trim brackets.
3. Install the interior as described below:
   a. Thread the provided elevating nuts on the enclosure studs.
   b. Set the interior on the enclosure studs. (See Figure 1 on page 10).
   c. Tighten the flange nuts against the interior side rails until the rails are against the back of the enclosure.
   d. Remount the interior trim after wiring.
4. If used as service entrance equipment, neutral bonding is required. See the “Neutral Bonding Strap Installation” instructions on page 11.
5. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.



Flush Mounting (Enclosure Recessed in Wall)

1. Mount the enclosure as instructed in the NEMA PB 1.1 standards publication.
2. Remove the interior trim from the trim brackets.
3. Install the interior as described below:
   a. Thread the provided elevating nuts on the enclosure studs.
   b. Set the interior on the enclosure studs (see Figure 1 on page 10). Place the flange nuts onto the enclosure studs, but do not tighten.
   c. Adjust the elevating nuts so that the lip of the interior trim is approximately 0.25 inches (6.35 mm) from wall line.
   d. Tighten the flange nuts against the side rails.
   e. Remount the interior trim after wiring.
4. If used as service entrance equipment, neutral bonding is required. See the “Neutral Bonding Strap Installation” instructions on page 11.
5. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.

Neutral Bonding Strap Installation

The neutral bonding strap should be used only when the panelboard is **installed** as service equipment.

To properly bond the neutral to the panelboard, follow the instructions for either “125 A or 250 A Maximum NF Panelboards”, “400 A or 600 A Maximum NF Panelboards”, or “800 A Maximum NF Panelboards” below, and on pages 12–14.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Turn off all power supplying this equipment before working on or inside the equipment.
- The main bonding strap should be used only when the panelboard is installed as service equipment.
- Do not mix the mounting screws with the interior trim screws.

Failure to follow these instructions will result in death or serious injury.

NOTE: The bonding strap parts are found in the bag assembly provided with the interior.

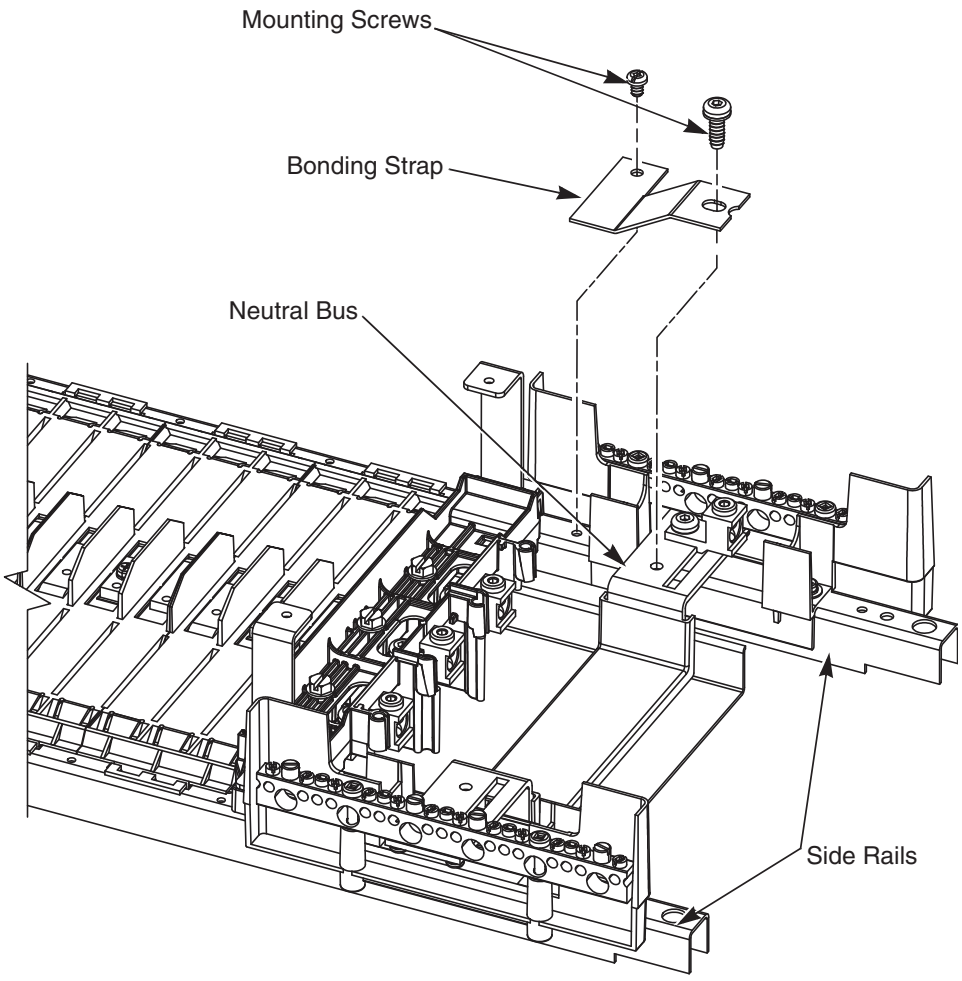
125 A or 250 A Maximum NF Panelboards

To install a neutral bonding strap on a 125 A or 250 A maximum NF panelboard, refer to Figure 2 and follow the instructions below.



1. Align the bonding strap on the side rail, as pictured.

   NOTE: For some applications, it may be necessary to remove the lug (not pictured) before installing the bonding strap.

2. Insert the two mounting screws, as pictured. Tighten the 10-32 screw to 10–12 lb-in (1.1–1.4 N•m) and the 1/4-20 screw to 25–30 lb-in (2.8–3.4 N•m).

   NOTE: If the lug was removed in Step 1, reinstall it on top of the bonding strap. Use the 1/4-20 x 3/4 in. mounting screw. Lug mounting screws are provided in the bonding strap bag assembly.

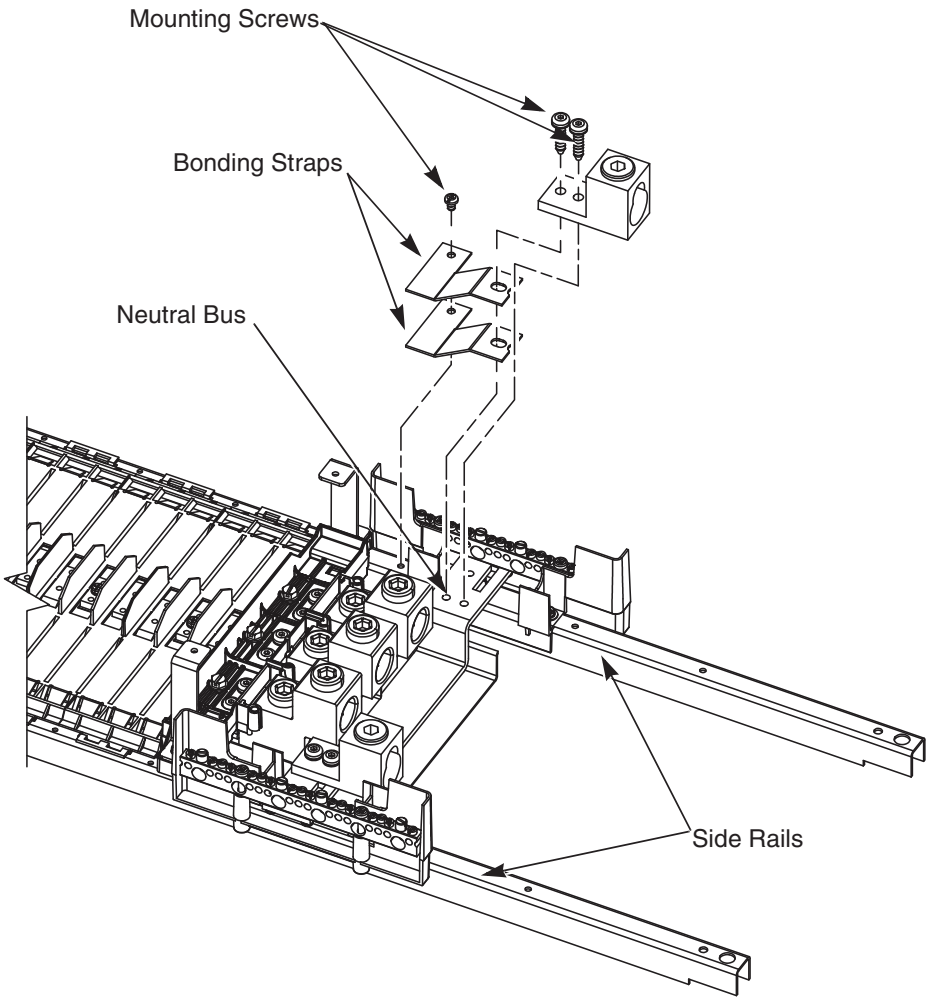
400 A or 600 A Maximum NF Panelboards

To install a neutral bonding strap on a 400 A or 600 A maximum NF panelboard, refer to Figure 3 and follow the instructions below.



1. Align the two bonding straps on the side rail, as pictured.

   NOTE: For some applications, it may be necessary to remove the lug before installing the bonding strap.

2. Insert the three mounting screws, as pictured. Tighten the 10-32 screw to 10–12 lb-in (1.1–1.4 N•m) and the two 1/4-20 screws to 60–65 lb-in (6.8–7.3 N•m).

   NOTE: If the lug was removed in Step 1 above, reinstall it on top of the bonding strap. Use the 1/4-20 x 1 1/8 in. mounting screws. Lug mounting screws are provided in the bonding strap bag assembly.

800 A Maximum NF Panelboards

To install a neutral bonding strap on an 800 A maximum NF panelboard, refer to Figure 4 and follow the instructions below.

1. Align the two bonding straps on the side rail, as pictured.
2. Insert the two mounting screws, as pictured. Tighten the 10-32 screw to 10–12 lb-in (1.1–1.4 N•m) and the 1/4-20 screw to 60–65 lb-in (6.8–7.3 N•m).

ECB, EDB, EGB, and EJB Circuit Breaker Installation and Removal

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly-rated voltage sensing device to confirm that all power is off.
- All unused spaces must be filled with blank fillers.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

ECB, EDB, EGB, and EJB Circuit Breaker Installation

Refer to Figure 5 on page 16 for the following instructions:

1. Turn off all power to the panelboard.
2. Turn the breaker off.
3. Remove the interior trim.
4. With the bolt-on connector end of the circuit breaker slightly elevated, insert the mounting foot into the slot in the phase cover.
5. Rotate the breaker down and back until the captive screw(s) align with the tapped holes in the breaker connectors.
6. Engage the screws into the branch connector hole and tighten it to 20–30 lb-in (2.3–3.4 N•m).
7. Install the load wire.
8. Reinstall the interior trim.

ECB, EDB, EGB, and EJB Circuit Breaker Removal

Refer to Figure 5 on page 16 for the following instructions:

1. Turn off all power to the panelboard.
2. Remove the interior trim.
3. Turn the breaker off.
4. Remove the load wire.
5. Loosen the screw(s) in the breaker connector and lift the breaker off of the panelboard.
6. Reinstall the interior trim.

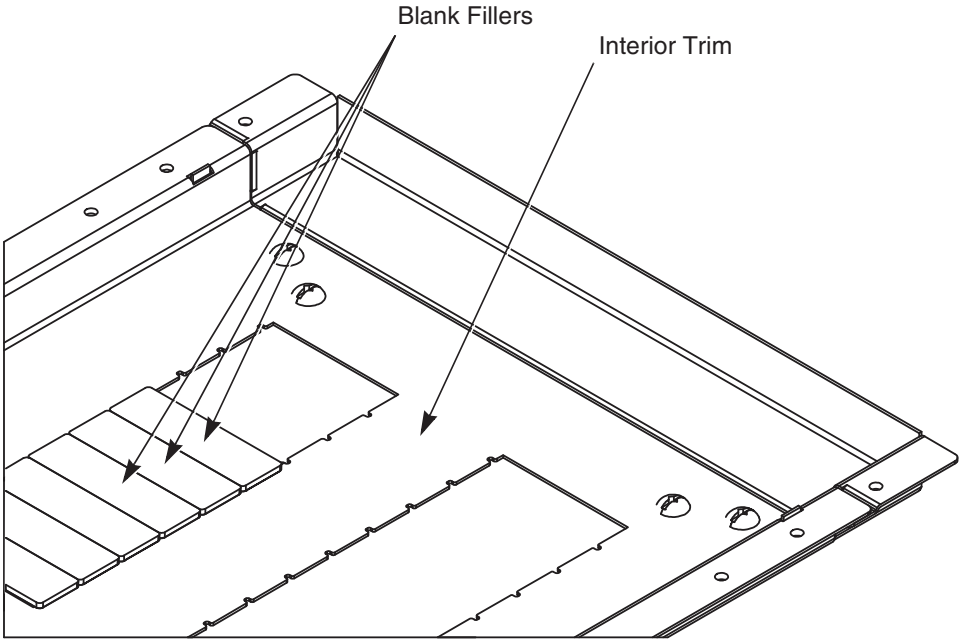
Interior Trim Preparation



⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Before energizing the panelboard, all unused spaces must be filled with blank fillers.
- Replace all devices, doors, and covers before energizing this equipment.

Failure to follow this instruction will result in death or serious injury.

Short Circuit Current Rating for Main Lug Interiors with Sub-Feed or Feed-Through Lugs

Main lug interiors equipped with sub-feed or feed-through lugs, where the device feeding the interior is unknown or not a Square D device, are rated to 25,000 RMS symmetrical amperes at 600Y/347 Vac maximum for three cycles. Use of one of the Square D circuit breakers of the correct ampere rating, listed as main circuit breakers on page 19, ahead of these lugs will result in a rating equal to that of the circuit breaker.

CAUTION

HAZARD OF EQUIPMENT DAMAGE

Use only one wire per phase for incoming circuit breaker connections when the integral LH main circuit breaker is upstream of the feed-through lugs.

Failure to follow these instructions can result in equipment damage.

CE Marking

Interiors with the “CE” mark meet the IEC 60439-1 standard.

Hazard Categories and Special Symbols

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates an imminently hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a potentially hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a potentially hazardous situation which, if not avoided, **can result in** minor or moderate injury.

NOTICE

NOTICE is used to address practices not related to physical injury. The safety alert symbol is not used with this signal word.

NOTE: Provides additional information to clarify or simplify a procedure.

Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

Introduction

This bulletin contains instructions for installing Square D™ brand NQ circuit breaker panelboards and QONQ load centers. These panelboards and load centers are Underwriters Laboratories (cULus) listed and accept QO™ and QOB branch circuit breakers.

For technical support on the installation of this panelboard, contact the Square D/Schneider Electric Customer Information Center at (1-888-778-2733).

See the labels on the equipment for rating and safety information. Additional equipment labels are provided with this document.

Safety Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462 or NOM-029-STPS.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn OFF all power supplying this equipment before working on or inside the equipment.
- Always use a properly-rated voltage sensing device to confirm all power is OFF.
- Read and understand this entire instruction bulletin and the included NEMA PB 1.1 standards publication before installing, operating, or maintaining this equipment.
- Local codes vary, but are adopted and enforced to promote safe electrical installations. A permit may be needed to do electrical work, and some codes may require an inspection of the electrical work.
- Replace all devices, doors and covers before turning ON power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Installation

This section provides instructions for the following NQ panelboard and QONQ load center procedures:

- “Interior Mounting for Square D Brand Enclosures” on page 6
- “Neutral Bonding Strap/Cable Installation” on page 9
- “QO and QOB Circuit Breaker Installation and Removal” on page 12
- “Circuit Breaker Reset Instructions” on page 15
- “Interior Trim Preparation” on page 16

Interior Mounting for Square D Brand Enclosures

A separate standards publication, titled “General Instructions for Proper Installation, Operation, and Maintenance of Panelboards Rated 600 Volts or Less” (NEMA PB1.1), has been provided with this equipment. Familiarize yourself with the content of this document before proceeding with any of the following procedures.

If you did not receive a copy of this document, or if you have any questions regarding this equipment, contact your local distributor or Schneider Electric representative.

NOTICE

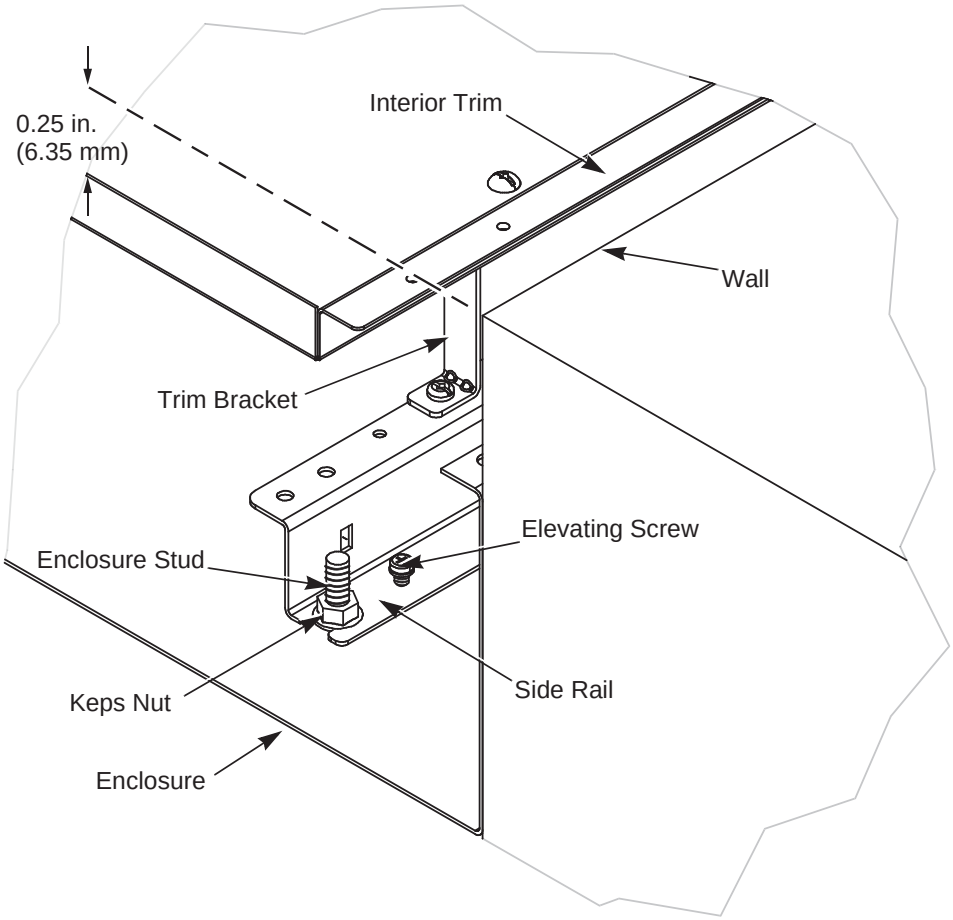
HAZARD OF EQUIPMENT DAMAGE DUE TO LOOSE CONNECTIONS

- Ensure all connections are properly tightened.
- Refer to the torque information label provided on the panelboard before tightening the connections.

Failure to follow these instructions can result in equipment damage.

To properly mount and install the NQ panelboard or QONQ load center interior, please refer to the NEMA PB 1.1 standards publication, and follow the instructions below for either ““Surface Mounting (Enclosure Mounted on Wall)” on page 7” or ““Flush Mounting (Enclosure Recessed in Wall)” on page 7.”

Surface Mounting (Enclosure Mounted on Wall)



1. Mount the enclosure as instructed in the NEMA PB 1.1 standards publication.
2. Remove the interior trim from the trim brackets.
3. Install the interior as described below:
   a. Set the interior on the enclosure studs. An elevating screw is not required (See Figure 1 on 8).
   b. Tighten the keps nuts against the interior side rails until the rails are against the back of the enclosure.
   c. Remount the interior trim after wiring.
4. If used as service entrance equipment, neutral bonding is required. See the “Neutral Bonding Strap/Cable Installation” instructions on page 9.
5. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.

Flush Mounting (Enclosure Recessed in Wall)

1. Mount the enclosure as instructed in the NEMA PB 1.1 standards publication.
2. Remove the interior trim from the trim brackets.
3. Install the interior as described below:
   a. Thread the (4) 10-32 x .875 in. self-tapping, elevating screws provided with the flush trim into the side rails.
   b. Set the interior on the enclosure studs (see Figure 1 on 8). Place the keps nuts onto the enclosure studs, but do not tighten.
   c. Adjust the screws so that the lip of the interior trim is approximately 0.25 inches (6.35 mm) from wall line.
   d. Tighten the keps nuts against the side rails.
   e. Remount the interior trim after wiring.
4. If used as service entrance equipment, neutral bonding is required. See the “Neutral Bonding Strap/Cable Installation” instructions on page 9.
5. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.

Neutral Bonding Strap/Cable Installation

The neutral bonding strap/cable should be used only when the panelboard is **installed** as service entrance equipment.

To properly bond the neutral to the panelboard, follow the instructions for either “100 or 250 A Maximum NQ Panelboards” or “400 or 600 A Maximum NQ Panelboards and QONQ Load Centers” below and on page 11, respectively.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462 or NOM-029-STPS.
- Turn OFF all power supplying this equipment before working on or inside the equipment.
- The main bonding strap/cable should be used only when the panelboard is installed as service entrance equipment.
- Do not mix the mounting screws with the interior trim screws.

Failure to follow these instructions will result in death or serious injury.

NOTE: The bonding strap/cable parts are found in the bag assembly provided with the interior.

100 or 250 A Maximum NQ Panelboards

To install a neutral bonding strap on a 100 or 250 A maximum NQ panelboard, refer to Figure 2 and follow the instructions below.

1. Align the bonding strap on the side rail, as pictured.

   NOTE: For some applications, it may be necessary to remove the lug (not pictured) before installing the bonding strap.

ENGLISH

2. Insert the two mounting screws, as pictured. Tighten the 10-32 screw to 10–12 lb-in (1.1–1.4 N•m) and the 1/4-20 to 25–30 lb-in (2.8–3.4 N•m).

   NOTE: If the lug was removed in Step 1 above, reinstall it on top of the bonding strap. Use the 1/4-20 x 11/16 in. mounting screw with feed-through lug, sub-feed lug, sub-feed breaker, or 200% neutral applications. Use the 1/4-20 x 7/8 in. lug mounting screw with 200% neutral on 225 A applications with feed-through lug, sub-feed lug, or sub-feed circuit breaker applications. Lug mounting screws are provided in the bonding strap bag assembly.

400 or 600 A Maximum NQ Panelboards and QONQ Load Centers

To install a neutral bonding cable on a 400 or 600 A maximum NQ panelboard and QONQ load center, refer to Figure 3 and follow the instructions below.

1. Align the lug on the side rail mounting hole, as pictured.
2. Tighten the lug mounting screw against the side rail to 10–12 lb-in (1.1–1.4 N•m).
3. Align the bonding cable, as pictured, and insert it into the lug and neutral mounting holes.
4. Tighten both the lug wire binding screw and the neutral wire binding screw to 45–50 lb-in (5.1–5.6 N•m).

QO and QOB Circuit Breaker Installation and Removal

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462 or NOM-029-STPS.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn OFF all power supplying this equipment before working on or inside equipment.
- Always use a properly-rated voltage sensing device to confirm that all power is OFF.
- All unused spaces must be filled with blank fillers.
- Replace all devices, doors and covers before turning ON power to this equipment.

Failure to follow these instructions will result in death or serious injury.

QO and QOB Breaker Installation

Refer to Figure 4 on 14 for the following instructions:

1. Turn OFF all power to the panelboard.
2. Turn the breaker OFF.
3. Remove the interior trim.
4. Snap the wire terminal end of the circuit breaker onto the mounting rail.
5. Engage the branch connector.

   For QO Circuit Breakers:

   a. Push inward until the plug-on jaws fully engage the branch connector.

   For QOB Circuit Breakers:

   a. Push inward until the breaker connector is centered on the branch connector mounting hole. Engage the screw into the branch connector hole and tighten it to the torque values shown on the interior wiring and torque diagram.

6. Install the load wire.
7. Reinstall the interior trim.

QO and QOB Breaker Removal

Refer to Figure 4 on 14 for the following instructions:

1. Turn OFF all power to the panelboard.
2. Remove the interior trim.
3. Remove the load wire.
4. Disengage the branch connector.

   For QO Circuit Breakers:

   a. Pull outward until the plug-on jaws fully disengage the branch connector.

   For QOB Circuit Breakers:

   a. Loosen the screw in the breaker connector and pull the breaker off of the branch connector.

ENGLISH

5. Snap the wire terminal end of the circuit breaker off of the mounting rail.
6. Reinstall the interior trim.

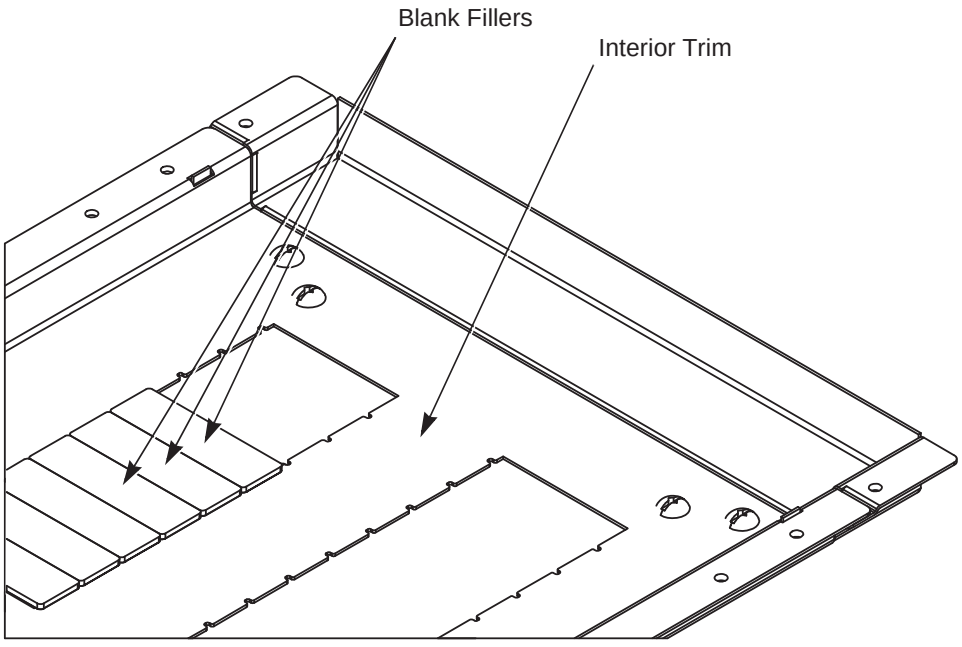
Interior Trim Preparation



⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462 or NOM-029-STPS.
- Before energizing the panelboard, all unused spaces must be filled with blank fillers.
- Replace all devices, doors, and covers before energizing this equipment.

Failure to follow this instruction will result in death or serious injury.

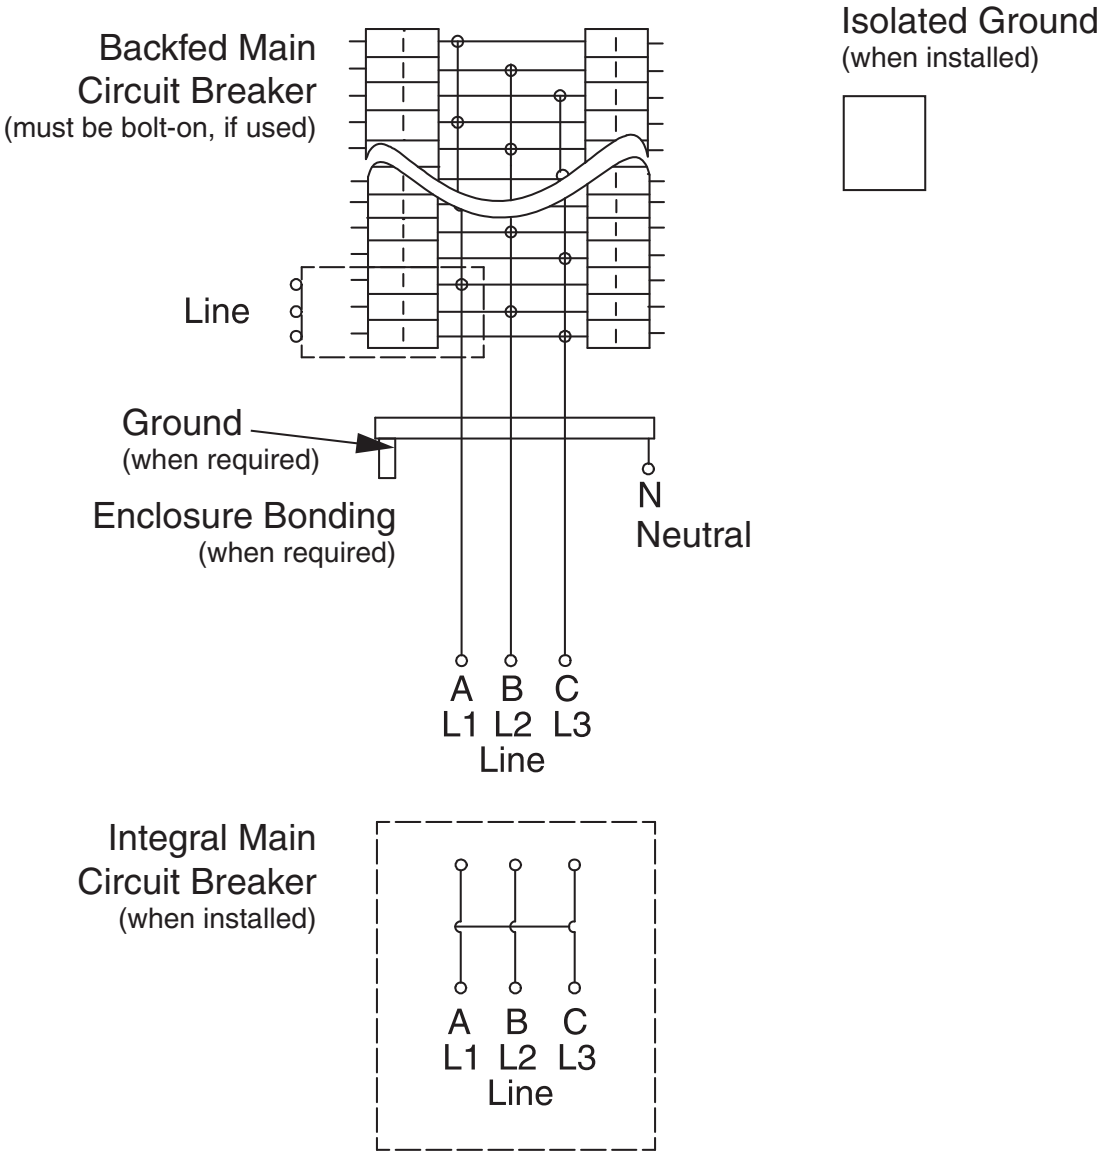
1 Additional information is provided on the panelboard. See the main circuit breaker rating, if used.

2 For this system, the neutral is not used and only circuit breakers rated 240 V AC minimum should be used. Do not use circuit breakers rated 120 V or 120/240 V AC.



3 For a grounded “B” phase system, only circuit breakers rated 240 V AC minimum should be used. Do not use circuit breakers rated 120 V or 120/240 V AC.

4 When wiring for a delta system, phases “A” and “C” must be 120 V to neutral, phase “B” 208 V to neutral. Connect only circuit breakers rated 240 V AC minimum. Do not use circuit breakers rated 120 V or 120/240 V to “B” phase.

1 For shown circuit breakers rated less than this maximum voltage, the indicated short circuit current rating also applies, but at the voltage rating of the circuit breaker.

2 Short circuit tests are conducted at 100–105% of the maximum rated voltage of the panelboard.

3 Suffixes HID, SWD, and SWN may also be applied to the applicable branch circuit breakers shown above. Suffix SWN may **not** be applied in combination with LC main breakers.

4 Where QO (B) circuit breakers are shown above, QO (B) H, QO (B) VH, and QH (B) circuit breakers may also be used.

5 Where QO (B) GFI circuit breakers are shown above, QO (B) EPD and/or QO (B) EPE circuit breakers may also be used. QO-EPE only comes in 3 pole construction.

6 Where QO (B) AFI circuit breakers are shown above, QO (B) CAFI circuit breakers may also be used.

7 To achieve selective coordination, the rating of the DJ main circuit breaker must be at least two times greater than the ampere rating of any branch circuit breaker.

Table 4: Short Circuit Current Rating[1] for Main Lug Interiors with Sub-Feed or Feed-Through Lugs

Maximum System Voltage AC	Maximum Current Rating	Branch Circuits	Application	Adder[2]	Maximum Short Circuit Current Rating[3]
240	100	18, 30	SFL and FTL	—	10,000
	225	30, 42, 54, 72, 84	SFL	6 inches (152.4 mm)	
		42	FTL	—	
		30, 54, 72, 84		6 inches (152.4 mm)	
	400	30, 42, 54, 72, 84	SFL	—	25,000
		30, 84	FTL	—	
		42, 54, 72		6 inches (152.4 mm)	
	600	30, 42, 54, 72, 84	FTL	12 inches (304.8 mm)	

1 This rating applies to main lug interiors, equipped with sub-feed or feed-through lugs, where the device feeding the interior is unknown or not a Square D brand device. Use of a Square D brand main circuit breaker ahead of these lugs will result in a rating equal to the rating of the breaker. Short circuit tests are conducted at 100–105% of the maximum rated voltage of the panelboard.

2 The adder is the additional length of the enclosure.

3 RMS symmetrical amperes, for three cycles.

CE Marking

Interiors with the "CE" mark meet the IEC 61439-1 and IEC 61439-2 standards.
Main lug interiors with the "CE" mark have been tested to withstand 10,000 RMS symmetrical amperes for 30 cycles.
Interiors with the "CE" mark are only approved for use with QOXD or QOBXD branch circuit breakers which carry the "CE" mark.

Appendix 2: Accessory Kits

An assortment of field-installable accessory kits are available for NQ panelboards:

- Equipment Ground Bar Kits
- Oversized Lug Kits for 100–250 A Panelboards
- Sub-Feed Lug Kits for 100–400 A Panelboards
- Main Lug Kits
  - — Mechanical Lug Kits—Aluminum
  - — Mechanical Lug Kits—Copper
  - — Versa-Crimp® Compression Lug Kits—Aluminum
  - — Versa-Crimp Compression Lug Kits—Copper

Equipment Ground Bar Kits

Equipment ground bar kits, suitable for copper or aluminum wire, meet the grounding needs of NQ panelboards and QONQ load centers.

Table 5: Equipment Ground Bar Kits Specifications

Panelboard		Use Ground Bar Kit Catalog Number	
Branch Circuit	**Mains Rating**	**Aluminum[1]**	**Copper[2]**
1–42	600 A Maximum	(1) PK27GTA	(1) PK27GTACU
54–84		(2) PK27GTA	(2) PK27GTACU

1 Aluminum bars suitable for 60° C or 75° C Copper or Aluminum conductors.

2 Copper bars suitable for 60° C or 75° C Copper conductors.

NOTE: Ground bar mounting locations are identified by the ground symbol ⏚ stamped into the backwall of the enclosure.

Foreword

This publication is a guide of practical information containing instructions for the proper installation, operation, and maintenance of panelboards rated 600 volts or less.

These instructions do not purport to cover all details or variations in equipment, nor to provide for every possible contingency regarding installation, operation, or maintenance.

It is recommended that work described in this set of instructions be performed only by qualified personnel familiar with the construction and operation of panelboards and that such work be performed only after reading this complete set of instructions. For specific information not covered by these instructions, you are urged to contact the manufacturer of the panelboard directly.

In the preparation of this standards publication input of users and other interested parties has been sought and evaluated. Inquiries, comments, and proposed or recommended revisions should be submitted to the concerned NEMA product section by contacting the following: These recommendations will be reviewed periodically and updated as necessary.

Senior Technical Director, Operations

Publication PB 1.1- 2013 revises and supersedes PB 1.1-2007.

This standards publication was developed by the Panelboard and Distribution Board Product Group of the LVDE Section. Product Group approval of the standard does not necessarily imply that all Product Group members voted for its approval or participated in its development. At the time it was approved, the Product Group was composed of the following members:

Eaton Corporation.—Pittsburgh, PA
GE Industrial Solutions—Plainville, CT
Hubbell, Inc.—Orange, CT
Milbank Manufacturing Company—Kansas City, MO
Penn Panel & Box Company—Collingdale, PA
Reliance Controls Corporation—Racine, WI
Siemens Industry, Inc.—Norcross, GA
Schneider Electric —Palatine, IL

Section 1
SCOPE

This publication covers single panelboards or groups of panel units suitable for assembly in the form of single panelboards, including buses, and with or without switches or automatic overload protective devices (fuses or circuit breakers), or both. These units are used in the distribution of electricity at 600 volts and less with:

1600—ampere mains or less
1200—ampere branch circuits or less

Specifically excluded are live-front panelboards, panelboards employing cast enclosures for special service conditions, and panelboards designed primarily for residential and light commercial service equipment.

Section 3
GENERAL

WARNING—HAZARDOUS VOLTAGES IN ELECTRICAL EQUIPMENT CAN CAUSE SEVERE PERSONAL INJURY OR DEATH. UNLESS OTHERWISE SPECIFIED, INSPECTION AND MAINTENANCE SHOULD ONLY BE PERFORMED ON PANELBOARDS AND EQUIPMENT TO WHICH POWER HAS BEEN TURNED OFF, DISCONNECTED AND ELECTRICALLY ISOLATED SO THAT NO ACCIDENTAL CONTACT CAN BE MADE WITH ENERGIZED PARTS. FOLLOW ALL MANUFACTURER'S WARNINGS AND INSTRUCTIONS.

Safety-related work practices, as described in NFPA 70E, should be followed at all times.
All requirements of the *National Electrical Code*® NFPA 70 should be followed.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE PANELBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE COMPONENTS DURING INSTALLATION OR MAINTENANCE.

3.1 SUCCESSFUL OPERATION OF PANELBOARDS

The successful operation of panelboards is dependent upon proper installation, operation, and maintenance. Neglecting fundamental installation and maintenance requirements may lead to personal injury, death, or damage to electrical equipment or other property.

3.2 QUALIFIED PERSONNEL

Installation, operation, and maintenance of panelboards should be conducted only by qualified personnel.

3.3 DEFINITION OF QUALIFIED PERSONNEL

For purposes of these guidelines, a qualified person is one who is familiar with the installation, construction, and operation of the equipment and the hazards involved. In addition, the person is:

3.3.1 Requirements

Knowledgeable of the requirements of the *National Electrical Code*® and of all other applicable codes, laws, and standards.

3.3.2 Established Safety Practices

Trained and authorized to test, energize, clear, ground, tag, and lockout circuits and equipment in accordance with established safety practices.

3.3.3 Protective Equipment

Trained in the proper care and use of protective equipment such as rubber gloves, hard hat, safety glasses or face shields, and flash resistant clothing in accordance with established safety practices.

3.3.4 First Aid

Trained in rendering first aid.

3.4 SUITABLE RATINGS

Verify that all equipment being installed has ratings suitable for the installation.

Section 4
INSTALLATION OF PANELBOARD CABINETS (BOXES)

4.1 INSTALLATION INSTRUCTIONS

Installation of the cabinet in a neat and workmanlike manner. Follow the manufacturer's installation instructions.

4.2 LOCATION IN BUILDING

Locate the cabinet so that it is readily accessible and not exposed to physical damage.

4.3 FLAMMABLE MATERIAL

Locate the cabinet well away from flammable material.

4.4 UNUSUAL SERVICE CONDITIONS

Do not locate the cabinet where it will be exposed to ambient temperatures above 40°C (104°F), corrosive or explosive fumes, dust, vapors, dripping or standing water, abnormal vibration, mechanical shock, high humidity, tilting, or unusual operating conditions, unless the cabinet/panelboard combination has been designed and so identified by the manufacturer for these conditions.

4.5 INDOOR DAMP LOCATIONS

Locate or shield the cabinet so as to prevent moisture and water from entering and accumulating therein. Mount the cabinet so that there is at least 1/4 inch of air space between the cabinet and the wall or other supporting surface.

4.6 WET LOCATIONS

Cabinets should be specifically approved for wet locations. Mount the cabinet so that there is at least 1/4 inch of air space between the cabinet and the wall or other supporting surface.

4.7 CLEARANCE FROM CEILING

Do not locate the cabinet against a non-fireproof ceiling; allow a space of 3 feet between the ceiling and cabinet unless an adequate fireproof shield is provided.

4.8 SPACE AROUND THE CABINET

When selecting a location, provide sufficient access and working space around the cabinet (see Section 110.26 of the *National Electrical Code*®). The width of the working space in front of the panelboard should be at least 30 inches, or the width of the cabinet, whichever is greater, and this space should not be used as storage. The working space should have adequate lighting and a minimum head room of 6 feet 6 inches.

4.9 MOUNTING OF CABINET

The cabinet should be reliably secured to the mounting surface. Do not depend on wooden plugs driven into holes in masonry, concrete, plaster, or similar materials. (See Section 110.13 of the *National Electrical Code*®.)

© 2014 National Electrical Manufacturers Association

4.10 FLUSH MOUNTING IN WALL

In walls of concrete, tile, or other noncombustible material, install the cabinet so that its front edge will not set back more than 1/4 inch from the finished surface. In walls of wood or other combustible material, cabinets should be flush with or project beyond the finished surface. (See Section 312.3 of the *National Electrical Code*®.)

4.11 UNUSED OPENINGS IN CABINET

Effectively close unused openings in the cabinet to provide protection which is substantially equivalent to that afforded by the wall of the cabinet.

4.12 GROUNDING OF PANELBOARD CABINETS

Ground the cabinet as specified in Article 250 of the *National Electrical Code*®. When the cabinet contains service equipment, it is necessary to bond the cabinet to the grounded (neutral) service conductor.

© 2014 National Electrical Manufacturers Association

Section 5
INSTALLATION OF CONDUIT AND CONDUCTORS

5.1 CONDUITS INSTALLATION

Conduits should be installed so as to prevent moisture or water from entering and accumulating within the enclosure. Provision should be made to protect conductors from abrasion in accordance with Article 312 of the *National Electrical Code*®.

5.2 KNOCKOUTS REMOVAL

Knockouts should be removed as follows:

IMPORTANT—Remove knockouts, ONE AT A TIME, alternating INWARD and OUTWARD.

5.2.1 First Step—Remove Center Knockout

Remove center knockout INWARD.

5.2.1.1 Screwdriver Blade

Place screwdriver blade against point farthest from tie and strike INWARD (Figure 1). Bend back and forth to break tie.

5.2.2 Next Step—Remove Rings

Remove rings ONE AT A TIME without straining remaining rings.

5.2.2.1 Pry First Ring

Pry first ring OUTWARD with screwdriver midway between ties, using pliers flat against box under screwdriver (Figure 2). Bend ring sections OUTWARD with pliers, then back and forth to break ties (Figure 5-3).

5.2.2.2 Second Ring

Remove second ring INWARD by striking screwdriver (with blade against point midway between ties) then breaking ring sections inward and back and forth to break ties.

5.3 *NATIONAL ELECTRICAL CODE*®, ARTICLE 300

Refer to the *National Electrical Code*®, Article 300 for proper wiring methods. See 6.7 for making proper connections.

5.4 CONDUCTOR LENGTH

Keep conductor length to a minimum within the wiring gutter. Excessive conductor length will result in additional heating and may result in overheating. However, conductors should be long enough to reach the terminal location in a manner that avoids strain on the terminal.

5.5 EXERCISE CARE

Exercise care to maintain the largest practical bending radius of conductors; otherwise the insulation may be damaged and terminal connections may become loosened. Deflection of conductors shall comply with *NEC*® Section 312.6.

© 2014 National Electrical Manufacturers Association

5.6 *NATIONAL ELECTRICAL CODE*®, SECTION 725.136

Refer to the *National Electrical Code*®, Section 725.136 for the separation requirements for conductors of Class 2 and Class 3 remote-control, signaling and power-limited circuits.

Section 6
INSTALLATION OF PANELBOARD

6.1 PROPER STORAGE

Store the panelboard in a clean, dry place located so that mechanical damage from work personnel in the area is not likely to happen.

6.2 UNPACKING

Care should be exercised in unpacking the panelboard to prevent damage and loss of instruction materials and loose parts.

6.3 INSPECTION

Check for shipping damage and check to make sure that the panelboard is the correct one for installation in the cabinet.

6.4 CARE

Care should be taken to protect the panelboard internal parts from contamination during the installation process.

6.4.1 Cleaning

Clean the cabinet of all foreign materials. If parts at connection points are spattered with cement, plaster, paint, or other foreign material, remove the foreign materials with great care to avoid damage to the plating.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE PANELBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE PANELBOARD COMPONENTS DURING INSTALLATION OR MAINTENANCE.

6.5 MANUFACTURER'S INSTRUCTIONS

Carefully follow the manufacturer's instructions and labels.

6.6 INSTALLATION

6.6.1 Alignment Devices

Adjust the alignment devices where provided.

6.6.2 Panelboard

Install the panelboard, finalize its alignment, and tighten it securely in the cabinet.

6.6.3 Flange of Deadfront Shield

Unless otherwise instructed by the manufacturer, adjust the panelboard so that the flange of the deadfront shield is no more than 3/16 inch from (1) the front of the cabinet for surface mounting or (2) the surrounding wall surfaces for flush mounting.

© 2014 National Electrical Manufacturers Association

6.7 LINE AND BRANCH CONDUCTORS

Connect Line and Branch Conductors

6.7.1 Conductors

Use care in stripping insulation from conductors so as not to nick or ring the conductor. For aluminum, clean all oxide from the stripped portion and apply an antioxide compound.

6.7.1.1 Wiring Gutters

Distribute and arrange conductors neatly in the wiring gutters. (See Section 5.)

6.7.1.2 Types and Temperature Ratings

Care should be exercised to ensure that the types and temperature ratings of conductors being installed in the panelboard are suitable for use with the terminals, which have been provided.

6.7.1.3 Tighten All Terminals

Use the manufacturer's torque values. (See 7.1).

6.8 PANELBOARD GROUNDING AND BONDING

Ground the panelboard cabinet in accordance with 4.12. (See Section 408.40 of the *National Electrical Code*®.)

6.8.1 Equipment Grounding Conductors

Where separate equipment grounding conductors are used, prepare equipment grounding conductors in accordance with 6.7.1 and connect them to the equipment grounding terminal bar. Check to be sure that the terminal bar is securely bonded to the cabinet or panelboard frame and that it is not connected to the neutral bar except at service equipment (as permitted in Section 250.28 of the *National Electrical Code*®) or at separately derived systems (as permitted in Section 250.30 of the *National Electrical Code*®).

NOTE—An equipment grounding terminal bar is not always required. For example, when a properly installed metallic raceway is used as the equipment grounding path or when the grounded conductor terminals (neutral bar) complies with the conditions of the last sentence of Section 408.40 of the *National Electrical Code*®.

6.9 PROPER TYPE OR CLASS AND RATING

When installing circuit breakers or fuses, ensure that they are of the proper type or class and rating.

6.10 DEBRIS

Clean the cabinet of all debris, which has accumulated during the panelboard installation Ensure that all foreign materials, including cement, plaster and paint (overspray) are cleaned and removed. Remove all such materials with great care to avoid damage to conductors, plating, etc. (see 6.4.1).

6.11 STEPS IN SECTION 7

If the job is complete, perform the steps in Section 7 and then install the cabinet front (see Section 8).

© 2014 National Electrical Manufacturers Association

Section 7
STEPS TO BE TAKEN BEFORE ENERGIZING

7.1 ACCESSIBLE ELECTRICAL CONNECTIONS

Tighten all accessible electrical connections to the manufacturer's torque specifications. If such information is not provided with the equipment, consult the manufacturer.

7.2 BLOCKS AND PACKING MATERIALS

Make certain that all blocks and packing materials used for shipment have been removed from all component devices and the panelboard.

7.3 SWITCHES, CIRCUIT BREAKERS, AND OTHER OPERATING MECHANISMS

Manually exercise all switches, circuit breakers, and other operating mechanisms to make certain they operate freely. If devices with self-test function are installed, perform test and verify proper operation per the manufacturer's instructions.

Check the integrity of all electrical and mechanical interlocks and padlocking mechanisms. For key interlocked systems, assure that only the required number of keys are accessible to the operator.

7.4 SHORT CIRCUITS AND GROUND FAULTS

To make sure that the system is free from short circuits and ground faults, conduct an insulation resistance test phase to ground and phase to phase with the switches or circuit breakers in both the open and closed positions. If the resistance reads less than 1 megohm while testing with the branch circuit devices in the open position, the system may be unsafe and should be investigated. If after investigation and possible correction, low readings are still observed, the manufacturer should be contacted. Some electronic equipment (metering, SPD, etc.) may be damaged by this testing. Refer to the manufacturers equipment markings for guidelines.

7.5 GROUND FAULT PROTECTION SYSTEM

Test the ground fault protection system (if furnished) in accordance with the manufacturer's instructions. See Section 230.95 of the *National Electrical Code*® and NEMA PB 2.2, *Application Guide for Ground Fault Protective Devices for Equipment*.

7.6 ADJUSTABLE TIME CURRENT TRIP DEVICE SETTINGS

Set any adjustable time current trip device settings to the proper values.

NOTE—Experience has indicated that damage from overcurrent can be reduced if the devices used for overload and short-circuit protection are set to operate instantaneously (that is, without intentional time delay) at 115 percent of the highest value of phase current which is likely to occur as the result of any anticipated motor starting or welding currents.

7.7 GROUNDING CONNECTIONS

Check to determine that all grounding connections are properly made. If the panelboard is used as service equipment, make certain that the neutral, if present, is properly bonded to the cabinet.

© 2014 National Electrical Manufacturers Association

7.8 FOREIGN MATERIAL

Remove all foreign material from the panelboard and cabinet before installing the cabinet front. Make certain that all deadfront shields are properly aligned and tightened. Install the cabinet front in accordance with Section 8.

© 2014 National Electrical Manufacturers Association

Section 8
INSTALLATION OF CABINET FRONT

8.1 CABINET FRONT OR TRIM PACKAGE

The cabinet front or trim package is designed to prevent damage to the front during shipment and handling.

8.2 UNPACKING

Care should be used when unpacking and handling the cabinet front.

8.3 COVERS AND DOORS

Install covers, close doors, and make certain that no conductors are pinched and that all enclosure parts are properly aligned and tightened. Hinged covers or doors must open a minimum of 90 degrees when installed.

8.4 TOUCH-UP

A suitable paint or other corrosion-resistant finish should be applied to those places where the finish is damaged.

8.5 FRONT ALIGNMENT

The cabinet front may be provided with an adjusting means to align it squarely with the building even though the cabinet may be slightly out of plumb with the building.

© 2014 National Electrical Manufacturers Association

Section 9
ENERGIZING EQUIPMENT

WARNING—HAZARDOUS VOLTAGES IN ELECTRICAL EQUIPMENT CAN CAUSE SEVERE PERSONAL INJURY OR DEATH. ENERGIZING A PANELBOARD FOR THE FIRST TIME AFTER INITIAL INSTALLATION OR MAINTENANCE IS POTENTIALLY DANGEROUS.

9.1 QUALIFIED PERSONNEL

Only qualified personnel should energize equipment for the first time. If short circuit conditions caused by damage or poor installation practices have not been detected in the procedures specified in Section 7, serious personal injury and damage can occur when the power is turned on.

9.2 LOAD ON THE PANELBOARD

There should be no load on the panelboard when it is energized. Turn off all of the downstream loads.

9.3 ENERGIZED IN SEQUENCE

The equipment should be energized in sequence by starting at the source end of the system and working towards the load end. In other words, energize the main devices, then the feeder devices, and then the branch-circuit devices. Turn the devices on with a firm positive motion.

9.4 LOADS SUCH AS LIGHTING CIRCUITS, CONTACTORS, HEATERS, AND MOTORS

After all main, feeder, and branch circuit devices have been closed, loads such as lighting circuits, contactors, heaters, and motors may be turned on.

© 2014 National Electrical Manufacturers Association

Section 10
MAINTENANCE

10.1 MAINTENANCE PROGRAM

A maintenance program for panelboards should be conducted on a regularly scheduled basis in accordance with the following:

10.2 PANELBOARD WHICH HAS BEEN CARRYING ITS REGULAR LOAD FOR AT LEAST 3 HOURS

A panelboard which has been carrying its regular load for at least 3 hours just prior to inspection should be field tested by feeling the deadfront surfaces of circuit breakers, switches, interior trims, doors, and enclosure sides with the palm of the hand. If the temperature of these surfaces does not permit you to maintain contact for at least 3 seconds, this may be an indication of trouble and investigation is necessary. Thermographic (infrared) scanning has become a useful method of investigating thermal performance.

WARNING—HAZARDOUS VOLTAGES IN ELECTRICAL EQUIPMENT CAN CAUSE SEVERE PERSONAL INJURY OR DEATH. UNLESS OTHERWISE SPECIFIED, INSPECTION AND MAINTENANCE SHOULD ONLY BE PERFORMED ON PANELBOARDS TO WHICH POWER HAS BEEN TURNED OFF, DISCONNECTED AND ELECTRICALLY ISOLATED SO THAT NO ACCIDENTAL CONTACT CAN BE MADE WITH ENERGIZED PARTS. FOLLOW ALL MANUFACTURER'S WARNINGS AND INSTRUCTIONS.

Safety related work practices, as described in NFPA 70E, should be followed at all times.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE PANELBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE PANELBOARD COMPONENTS DURING INSTALLATION OR MAINTENANCE.

10.3 INSPECT PANELBOARD ONCE EACH YEAR

Inspect the panelboard once each year or after any severe short circuit.

10.4 ACCUMULATION OF DUST AND DIRT

If there is an accumulation of dust and dirt, clean out the panelboard by using a brush, vacuum cleaner, or clean lint-free rags. Avoid blowing dust into circuit breakers or other components. Do not use a blower or compressed air.

10.4.1 Visible Electrical Joints and Terminals

Carefully inspect all visible electrical joints and terminals in the bus and wiring system.

10.4.2 Conductors and Connections

Visually check all conductors and connections to be certain that they are clean and secure. Loose and/or contaminated connections increase electrical resistance which can cause overheating. Such overheating is indicated by discoloration or flaking of insulation and/or metal parts. Pitting or melting of connecting surfaces is a sign of arcing due to a loose or otherwise poor connection. Parts which show evidence of overheating or looseness should be cleaned and re-torqued or replaced if damaged. Tighten bolts and nuts at bus joints to manufacturer's torque specifications.

© 2014 National Electrical Manufacturers Association

CAUTION—DO NOT REMOVE PLATING FROM ALUMINUM PARTS IN JOINTS OR TERMINATIONS. DAMAGE TO PLATING CAN RESULT IN OVERHEATING. REPLACE DAMAGED ALUMINUM PARTS.

10.4.3 Fuse Clip Contact Pressure and Contact Means

Examine fuse clip contact pressure and contact means. If there is any sign of overheating or looseness, follow the manufacturer's maintenance instructions or replace the fuse clips. Loose fuse clips can result in overheating.

10.4.4 Plug Fuses

Re-tighten plug fuses.

10.4.5 Conditions Which Caused Overheating

Be sure that all conditions which caused the overheating have been corrected.

10.5 PROPER AMPERE, VOLTAGE, AND INTERRUPTING RATINGS

Check circuit breakers, switches, and fuses to ensure they have the proper ampere, voltage, and interrupting ratings. Ensure that non-current-limiting devices are not used as replacements for current-limiting devices. Never attempt to defeat rejection mechanisms which are provided to prevent the installation of the incorrect class of fuse.

10.5.1 Mechanisms Free and in Proper Working Order

Operate each switch or circuit breaker several times to ensure that all mechanisms are free and in proper working order. Replace as required. See NEMA AB-4 for maintenance of molded case circuit breakers.

10.6 OPERATION OF ALL MECHANICAL COMPONENTS

Check the operation of all mechanical components. Replace as required.

10.6.1 Switch Operating Mechanisms

Exercise switch operating mechanisms and external operators for circuit breakers to determine that they operate freely to their full on and off positions.

10.6.2 Integrity of Electrical and Mechanical Interlocks

Check the integrity of all electrical and mechanical interlocks and padlocking mechanisms. For key interlocked systems, assure that only the required number of keys are accessible to the operator.

10.6.3 Missing or Broken Parts

Whenever practical, check all devices for missing or broken parts, proper spring tension, free movement, corrosion, dirt, and excessive wear.

10.6.4 Manufacturer's Instructions

Adjust, clean, and lubricate or replace parts according to the manufacturer's instructions.

10.6.4.1 Clean Nonmetallic Light Grease or Oil

Use *clean* nonmetallic light grease or oil as instructed.

10.6.4.2 Molded Case Circuit Breakers

Do *not* oil or grease parts of molded case circuit breakers.

© 2014 National Electrical Manufacturers Association

10.6.4.3 Clean, Light Grease

If no instructions are given on the devices, sliding copper contacts, operating mechanisms, and interlocks may be lubricated with clean, light grease.

10.6.4.4 Excess Lubrication

Wipe off excess lubrication to avoid contamination.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE PANELBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE PANELBOARD COMPONENTS DURING INSTALLATION OR MAINTENANCE.

10.6.5 Accessible Copper Electrical Contacts, Blades, and Jaws

Clean and dress readily accessible copper electrical contacts, blades, and jaws according to the manufacturer's instructions when inspection indicates the need.

10.7 DAMAGED INSULATING MATERIAL AND ASSEMBLIES

Look for and replace damaged insulating material and assemblies where sealing compounds have deteriorated.

10.8 MOISTURE OR SIGNS OF PREVIOUS WETNESS OR DRIPPING

Look for any moisture or signs of previous wetness or dripping inside the cabinet.

NOTE—Condensation in conduits or dripping from outside sources is one known cause of panelboard malfunction.

10.8.1 Conduits Which Have Dripped Condensate

Seal off any conduits which have dripped condensate, and provide means for further condensate to drain away from the panelboard.

10.8.2 Cracks or Openings

Seal off any cracks or openings which have allowed moisture to enter the enclosure. Eliminate the source of any dripping on the enclosure and any other source of moisture.

10.8.3 Insulating Material Which is Damp or Wet

Replace or thoroughly dry and clean any insulating material, which is damp or wet or shows an accumulation of deposited material from previous wettings.

10.8.4 Component Devices Which Show Evidence of Moisture Damage

Inspect all component devices. Replace any component device which shows evidence of moisture damage or has been subjected to water damage or flooding. Additional information may be found in the NEMA document “Guidelines for Handling Water Damaged Electrical Products.”

10.9 BEFORE CLEANUP AND CORRECTIVE ACTION IS ATTEMPTED

In the event of water damage, e.g., flooding or sprinkler discharge, the manufacturer should be consulted before clean up and corrective action is attempted.

© 2014 National Electrical Manufacturers Association

10.10 SEVERE ELECTRICAL SHORT CIRCUIT

If a severe electrical short circuit has occurred, the excessive currents may have resulted in structural component and/or bus and conductor damage due to mechanical distortion, thermal damage, metal deposits, or smoke. Examine all devices and bus supports for cracks or breakage. The manufacturer should be consulted before cleanup and correction is attempted.

10.11 GROUND FAULT PROTECTION SYSTEM

Test the ground fault protection system (if furnished) in accordance with the manufacturer's instructions. See Section 230.95 of the *National Electrical Code*® and NEMA PB 2.2 *Application Guide for Ground Fault Protective Devices for Equipment.*

10.12 INSULATION RESISTANCE

Check insulation resistance (see 7.4) under any of the following conditions:

10.12.1 Severe Short Circuit

If a severe short circuit has occurred (see 10.10);

10.12.2 Parts Replaced

If it has been necessary to replace parts or clean insulating surfaces;

10.12.3 Panelboard Exposed to High Humidity

If the panelboard has been exposed to high humidity, condensation, or dripping moisture.

© 2014 National Electrical Manufacturers Association

Section 11
PERMISSIBLE LOADING OF PANELBOARDS

11.1 *NATIONAL ELECTRICAL CODE®*

In compliance with the *National Electrical Code*®, the normal continuous loads (3 hours or more) of panelboard circuits should be not more than 80 percent of the rating of the overcurrent protective device, unless the marking of the device indicates that it is suitable for continuous duty at 100 percent of its rating.

11.2 HARMONICS IN ELECTRICAL SYSTEM

Some types of electrical equipment cause harmonics in the electrical system, which may result in overheating. This condition should be considered when determining panelboard loading.

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

PELIGRO DE DESCARGA ELÉCTRICA, EXPLOSIÓN O DESTELLO POR ARQUEO

- Utilice equipo de protección personal (EPP) apropiado y siga las prácticas de seguridad eléctrica establecidas por su Compañia, consulte la norma 70E de NFPA.
- Solamente el personal eléctrico especializado deberá instalar y prestar servicio de mantenimiento a este equipo.
- Desenergice el equipo antes de realizar cualquier trabajo en él.
- Siempre utilice un dispositivo detector de tensión nominal adecuado para confirmar la desenergización del equipo.
- Vuelva a colocar todos los dispositivos, las puertas y las cubiertas antes de volver a energizar el equipo.

El incumplimiento de estas instrucciones podrá causar la muerte o lesiones serias.

RISQUE D'ÉLECTROCUTION, D'EXPLOSION OU D'ÉCLAIR D'ARC

- Portez un équipement de protection personnelle (ÉPP) approprié et observez les méthodes de travail électrique sécuritaire. Voir NFPA 70E.
- Seul un personnel qualifié doit effectuer l'installation et l'entretien de cet appareil.
- Coupez l'alimentation de l'appareil avant d'y travailler.
- Utilisez toujours un dispositif de détection de tension ayant une valeur nominale appropriée pour vous assurer que l'alimentation est coupée.
- Replacez tous les dispositifs, les portes et les couvercles avant de mettre l'appareil sous tension.

Si ces directives ne sont pas respectées, cela entraînera la mort ou des blessures graves.

Hazard Categories and Special Symbols

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates an imminently hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a potentially hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a potentially hazardous situation which, if not avoided, **can result in** minor or moderate injury.

NOTICE

NOTICE is used to address practices not related to physical injury. The safety alert symbol is not used with this signal word.

NOTE: Provides additional information to clarify or simplify a procedure.

Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

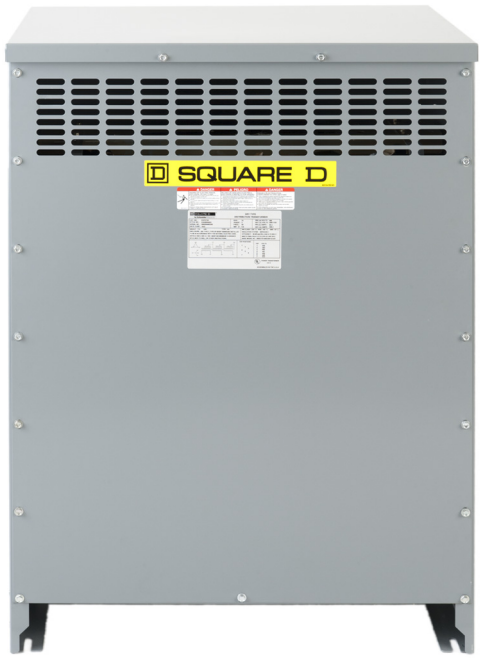
Section 1—Introduction

This instruction bulletin provides installation, operation and maintenance instructions for dry-type transformers 1000 volts and below for use in commercial and industrial applications.

NOTE: This bulletin should be used only by qualified personnel.



The following dry-type transformer product families are included in this instruction bulletin. Typical transformers are shown in Figures 1–6.

- Low Voltage Distribution Transformers, Three-phase and Single-phase
  - — General Purpose—50 and 60 Hz
  - — Energy Efficient (EE)—60 Hz
  - — Energy Efficient 2016 (EX)—60 Hz
  - — Non-linear Offering (NL, NP or NLP)—50 and 60 Hz
  - — Harmonic Mitigating Transformers (HM)—50 and 60 Hz
  - — Open Core and Coil (OC)
- Drive Isolation Transformers (DIT)
- Non-ventilated Transformers (NV)

Section 2—Safety Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E, NOM-029-STPS-2011, or CSA Z462.
- This equipment must be installed and serviced only by qualified electrical personnel.
- Perform such work only after reading and understanding all of the instructions contained in this bulletin.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Before performing visual inspections, tests, or maintenance on this equipment, disconnect all sources of electric power. Assume all circuits are live until they are completely de-energized, tested, and tagged. Pay particular attention to the design of the power system. Consider all sources of power, including the possibility of backfeeding.
- Always practice lock-out/tag-out procedures according to OSHA requirements.
- Carefully inspect your work area, and remove any tools and objects left inside the equipment.
- Replace all devices, doors, and covers before turning on power to this equipment.
- All instructions in this manual are written with the assumption that the customer has taken these measures before performing maintenance or testing.

Failure to follow these instructions will result in death or serious injury.

Codes and Standards

It is the responsibility of the users of this document to use qualified electrical personnel and to comply with applicable federal, state and local electrical codes when installing electrical products and systems.

This document adheres to the codes and standards as outlined by the National Fire Protection Association® (NFPA). Refer to NFPA 70: 2014 Edition National Electrical Code (NEC®).

Disclaimer Statement

Electrical equipment should be installed, operated, serviced and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

Section 3—Receiving, Handling and Storing

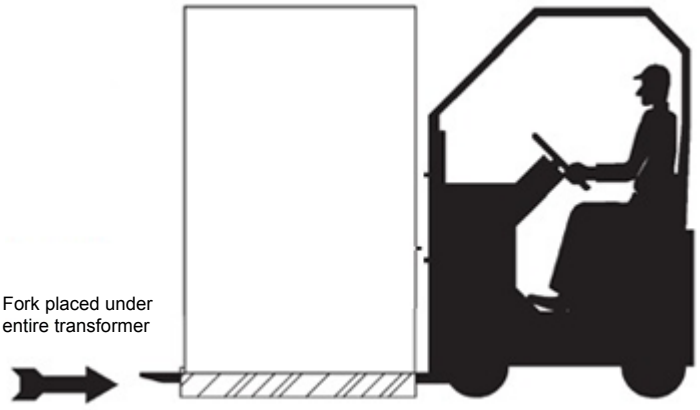
Receiving

1. Upon receipt, remove the packaging.
   - — Immediately inspect the new transformer for shipping damage.
   - — Refer to Replacement Parts and Accessories on page 41 for replacement parts, accessories (e.g., touch-up paint) and spare parts for minor damage.
2. Check the packing list against the product nameplate.
   - — Verify that the order and shipment align with each other and that the shipment is complete.

   NOTE: Follow Schneider Electric Conditions of Sale for shortages and errors.
3. Repackage the transformers for storage if they are not to be installed immediately.
   - — Cover all ventilation openings to protect against exposure to moisture, dust and contaminants.
   - — Leave packing materials intact until the transformers are ready to install.
4. Refer to “Conditions of Sale” for details regarding claims for equipment shortages and other errors. Contact your local Schneider Electric distributor for additional assistance.

Handling

Handle transformers carefully to avoid damage. Avoid subjecting the transformers to impact, jolting, jarring and rough handling. Ensure that transformers are transported in the upright position. When possible, transport transformers to the installation site while still mounted on their shipping pallets.



Verify that the weight of the transformer does not exceed the rated capacity of the handling equipment to be used.

Handling with Platform Dollies or Lifts, Pallet Jacks or Fork Trucks

Extreme care should be exercised when moving transformers from the bottom. See Figure 7.

- Use care to distribute the weight when transporting transformers using platform dollies, platform lifts, pallet jacks or fork trucks.
- Use hand trucks or forklifts only when the blades or forks are long enough to pass completely under the transformer enclosure or shipping pallet. Wider fork separation is preferred to distribute the weight of the unit evenly for increased stability.

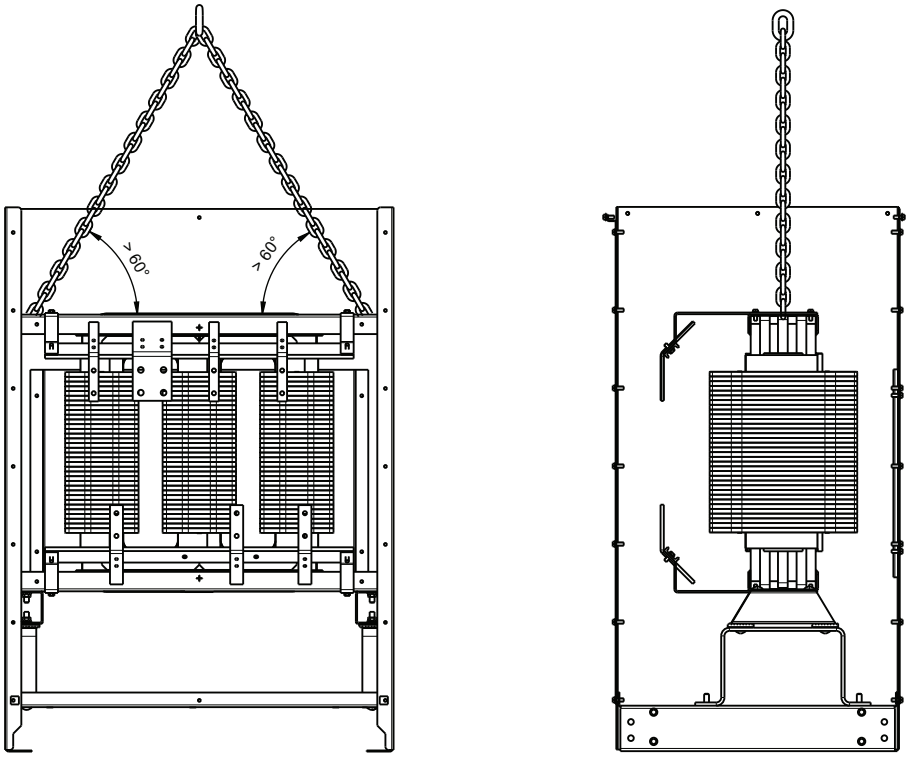
ENGLISH



Handling with Cranes: Using Cables, Chains or Straps

When lifting the transformer from above, the use of spreader bars with cables or chains is permissible. This will help avoid damage to the enclosure or equipment.

The enclosure can be removed to allow the units to be transported through small openings, lifting as the same means as shown in Figure 8 on page 11, Figure 9 on page 12, and Figures 10 and 11 on page 13. Refer to Figures 34 and 35 in Replacement Parts and Accessories on page 41 for exploded views of parts and accessories.

Ensure that the lifting cable pull angles are not less than 60 degrees from horizontal. See Figure 8 on page 11.

Handling Enclosure Styles D, H and K after Removal of the Shipping Pallet

Hand trucks and forklifts can access and move the transformer via the front and rear openings below the bottom of the base. See Figure 12. Follow the same handling instructions (beginning on page 10) as if the pallet is still attached.

Storing

Leave the packing material that encloses the transformer in place until the unit is ready for its final placement and wiring. This will help to protect the transformer enclosure and internal parts from dirt, water, moisture contamination and physical damage during storage. Provide extra measures to protect the transformer when the original packing material cannot be retained.

Store transformers indoors in a clean, dry, and heated building with uniform temperatures and adequate air circulation. If necessary, install electric heating to maintain a uniform temperature above the ambient temperature to prevent condensation.

Protect transformers from weather and contamination when it is not possible to store the transformers indoors.

Before energizing the transformer, complete the steps in Pre-commissioning/Pre-energizing Checks and Testing along with the following steps:

1. Test the insulation resistance if storage in a controlled environment was not feasible. Refer to Insulation Resistance on page 39.
2. Dry the unit if test levels are unacceptable:
   a. Use two heaters or lamps per coil at 120 V, 50 W to apply external heat to the coils.
   b. Mount the heater or lamp directly below the coils located at the front and rear of the core.

NOTE: Outdoor transformers are not weather resistant until they are properly and completely installed and energized. Treat outdoor transformers in exactly the same manner as indoor transformers until after they are installed.

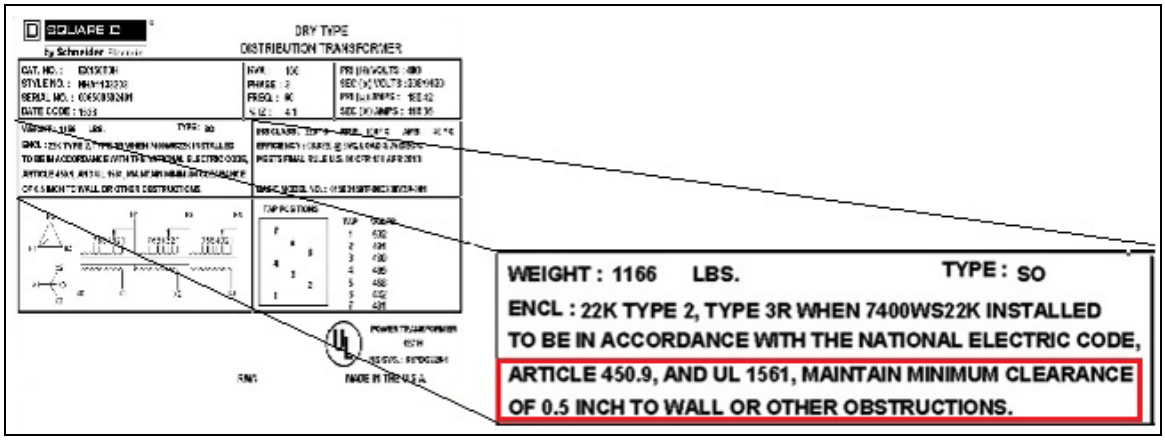
Section 4—Installation

Locating/Placing Ventilated and Non-ventilated Transformers

1. Remove all packaging material. Keep the shipping pallet attached to the transformer to assist with moving the unit to its final installation location.
2. Verify that the nameplate matches the description from the building layout drawings (kVA, primary and secondary voltages, etc.). See Figure 13.

Figure 13: Sample Nameplate



3. Locate the unit per the building's layout drawing.
4. Verify the environment is suitable for the enclosure type.
5. Ensure the location is readily accessible to qualified personnel (per NEC 450.13). Units located in the open can be mounted on walls, columns, or otherwise supported from structures.
6. Ensure adequate ventilation since it is essential to properly cool ventilated transformers. Refer to National Electrical Code (NEC®) Article 450.
   - The minimum distance is marked on Nameplate NEC 450.9. See Figure 14 on page 17.
   - Minimum distance varies by enclosure style. See the approval drawing from Schneider Electric for minimum distance.
   - Clean, dry air is desirable.
   - Filtered air may reduce maintenance if the location of the transformer presents a problem.

ENGLISH

Figure 14: Minimum Distance Marked on Nameplate NEC 450.9

7. Mount any accessories prior to installing the transformer when using wall or ceiling (trapeze) mounting.
   a. Observe the four mounting hole locations in each enclosure base.
   b. Obtain the actual dimensions via approval drawings from Schneider Electric.
   c. Secure the units using one of two mounting methods: without floor mounting brackets (Figures 15–16 and Figure 17 on page 18) or with floor mounting brackets (Figures 18 and 19 on page 18).
8. Place the transformer in final position.

All Enclosure Styles (D, E, F, H, K and J)

- Transformers Installed Indoors (Styles D, E, F, H, K and J):
  - — Completely enclosed or completely enclosed with ventilated openings; complies with NEC 450.21 (A) Exception
  - — Units greater than 112.5 kVA
  - — Have 428°F (220°C) or 392°F (200°C) insulation systems; complies with 450.21 (B) Exception No. 2

See Figure 20.

J			0.50 / 12.7
F			12 / 305

Transformers can be converted from Floor to Wall mounted (See Table 2 below and Figure 21 on page 20) or Floor to Trapeze mounted (See Table 3 and Figure 22 on page 21) using factory available kits. The kits are pre-punched to align with enclosure mounting holes; and, when the transformer is installed, holds the minimum clearance for the units. New Style K wall mounting bracket allows for 6 in. (152 mm) and 3 in. (76 mm) clearances, all other styles require a 6 in. (152 mm) clearance.

The factory kits do not include hardware, hardware must be supplied by the customer. Hardware includes the thread rod for trapeze mounting the transformers. The designer of record must size and choose the anchors and hardware because of the large variety of construction materials and techniques. Schneider Electric can not advise on the anchoring, the wall mounting, or sizing of rods for trapeze mounting.

Grounding

1. Permanently and adequately ground the enclosure and core assembly of dry-type transformers in accordance with NEC requirements.
   - — Windings may be grounded with consideration given to local conditions and in accordance with the NEC.
   - — The ground terminal bar must be UL listed for this purpose.
   - — In accordance with NEC 450.10, the terminal bar shall be bonded to the enclosure in accordance with NEC 250.12 and shall not be installed on or over any ventilated openings.
2. Connect the transformer, related accessories and components to ground in accordance with NFPA 70 (NEC).
3. Terminate all grounding and bonding conductors at a common equipment ground point on the enclosure.
4. Remove paint from around the area where the ground terminal bar is mounted to increase contact with enclosure parts.
   - — Enclosure Styles D, E and H: An area is available in the transformer's base to drill and mount the ground terminal bar.
   - — Enclosure Style K: Three pre-drilled holes are stamped ground to mount the ground terminal bar.
   - — Enclosure Style J: Two pre-drilled holes are stamped ground to mount the ground terminal bar.

Square D brand secondary lug kits include a four-conductor ground terminal bar. The bar can also be obtained as a separate device from Schneider Electric. Refer to Table 6 on page 45 and see Figure 24.

Seismic Qualifications

Seismic limits for dry-type low voltage transformers are obtained from tri-axle shake table test results that are conducted in accordance with the AC156 test protocol. Certifications are based on the location where units are installed and building codes governing the installation.

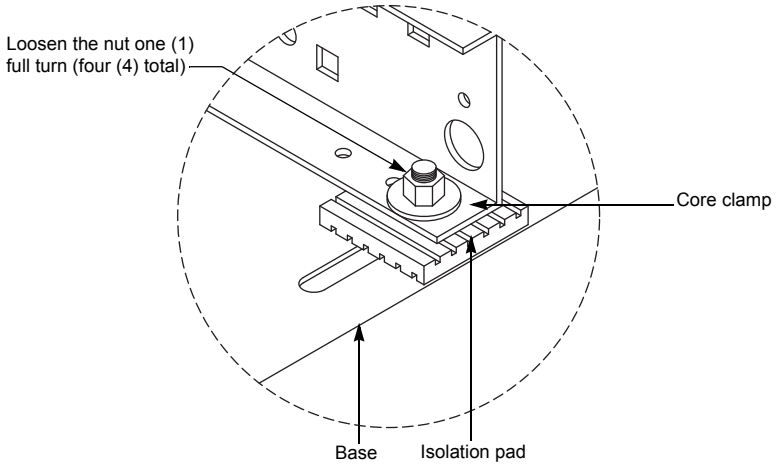
Building codes results are available for CBC 2001, CBC 2007, CBC 2010, IBC 2000, IBS 2003, IBC 2006, IBC 2009, NBC 2005, NBCC 2005, NBCC 2010, NFPA 5000, UBC 94, CBC 95, UBC97 and UFC 3-310-04.

Contact your local Schneider Electric distributor, or call 1-888-Square D (1-888-778-2733) to obtain the specific level of Sds, z/h and Ip for each enclosure style.

The levels supplied are based on the units being mounted and the notes on the approval drawings of each part number. Drawings are available that include mounting dimensions, mounting hole dimensions, overall dimensions, unit weight and approximate center of gravity location to assist in a seismic qualification. Contact your local Schneider Electric distributor, or call 1-888-Square D (1-888-778-2733) to obtain these drawings.

Other parties are responsible for detailing the equipment connection and anchorage requirements (including the lateral restraint system, if appropriate) for the given transformer installation. The installer and manufacturers of the anchorage and lateral restraint system are responsible for ensuring that the mounting requirements are met.

Sound/Vibration Control



The transformer has been designed to minimize the amount of audible sound produced. Sound isolation pads are secured between the transformer mounting bracket and the enclosure using bolts and nuts. The mounting hardware is tightened prior to shipment to prevent damage.

Loosen the nut one full turn to float the transformer on the isolation pads, thereby isolating the transformer from the enclosure. This will reduce audible sound levels even further. See Figures 25 and 26.

Figure 25: Loosening the Nut One Full Turn (Four Places) Label

Figure 26: Floating the Transformer on the Isolation Pads/Sound Damper

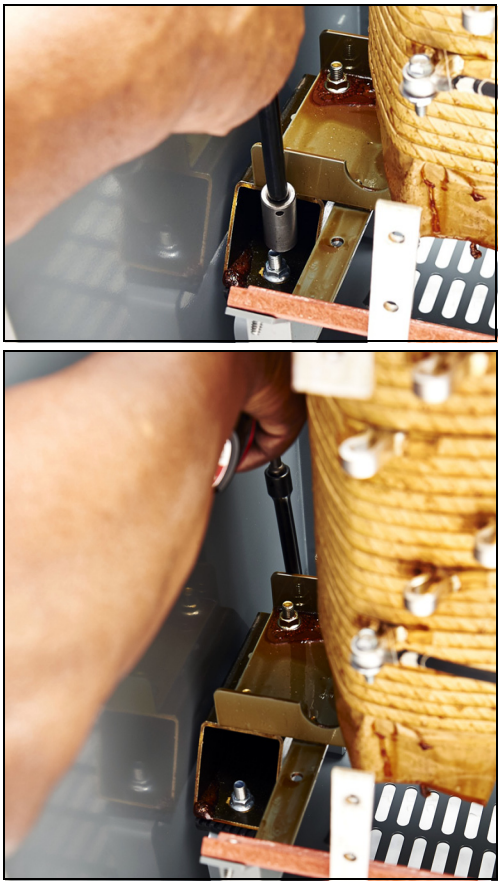
ENGLISH



In addition, the area where the transformer is located can affect the sound level:

- ❑ Try to avoid installing the transformer in a corner, narrow hall or in an area with smooth surfaces. Doing so can result in the sound being reflected and amplified.
- ❑ Securely fasten all the enclosure panels. Loose panels can result in rattling, thereby increasing the sound produced.
- ❑ Use flexible conduit, if possible.
- ❑ Ensure that the type of structure on which the transformer is mounted is strong enough to support the weight of the transformer.

Enclosure Style K

Enclosure Style K bolts are accessible from the front with an extension. See Figure 27.

Enclosure Styles D, E, H and J

Enclosure Styles D, E, H and J bolts are accessible from the front.

See Figure 26 on page 24 for the access for these enclosures.

Making Electrical Connections

- ❏ Use flexible raceways, conduits and connectors, when possible, as attachments to transformer enclosures. This will help to reduce audible noise generation.
- ❏ Adhere to NFPA 70 (NEC) and minimum wire bending space requirements for the transformer enclosure. As an industry standard, bundle associated phase, neutral and equipment grounding conductors together within the transformer enclosure.
- ❏ Always use a calibrated torque wrench to tighten electrical connectors and terminals. For additional guidance, refer to Standard UL468A.
- ❏ Ensure that raceways, conduits and connectors enter the enclosure only in an area shown on the drawings. Access points for each enclosure style are listed below:

- Enclosure Style D: (See Figure 28)
  - — Front section of the transformer
  - — Side and bottom access
- Enclosure Style E: (See Figure 28)
  - — Front section of the transformer

- ❏ Ensure that the side access complies with NEC 312.6 (A): Minimum Wire-Bending at Terminals. Bottom access must comply with NEC 312.6 (B): Minimum Wire-Bending Space at Terminals.
- ❏ Follow UL 1561 which requires that all lugs be suitable for 194°F (90°C). In addition, the conductors' temperature rating table must be 167°F (75°C) for the size to meet the current requirements of the overcurrent protection device and nameplate currents. Refer to Table 5 on page 44, Table 6 on page 45 and Table 7 on page 46 for a list of Square D lug kits, wire ranges by kVA and US voltage systems.
- ❏ Make sure that the contact surface is clean. This will minimize the possibility of a high resistance contact which could cause localized heating and possible premature failure. Refer to Connections and Contact Surfaces on page 38 for instructions to apply an approved electrical compound.
- ❏ Connect phases to proper terminals for proper motor-rotation. The phase diagram is shown on nameplate. The nameplate also shows the taps locations and voltage rating for each tap. See Figure 31.

❑ Connecting the source of supply to the transformer secondary is permitted by NE C450.11 where the installation conforms to the manufacturer's instructions.

When the source of supply is connected to the transformer secondary, the inrush current will increase. The overcurrent device should be selected based on NEC 450.3(B) using the 250% allowance in order to reduce the potential for nuisance tripping during energization. Secondary overcurrent protection will be required.

For source of supply side connections to a WYE configured transformer winding, do not make any connections to the supply side HO or XO terminals. See Figure 32.

Pre-commissioning/Pre-energizing Checks and Testing

Cleaning

1. Ensure that all of the packing material, including any packing material used inside the enclosure of the transformer used to support and protect the unit during shipping, have been removed.
2. Vacuum away as much dust as possible. Dust will act as a thermal insulating material which will increase the temperature of the unit and could possibly decrease operational life. Refer to Cleaning on page 38.

Visual and Mechanical Checks

Perform the following visual and mechanical checks below. In addition, refer to Performing Visual and Mechanical Checks on page 37 for a detailed listing of instructions.

- ❑ Visually inspect the transformer for physical damage. Repair any physical damage, if possible, and provide suitable protective barriers to prevent future damage.
- ❑ Compare the transformer nameplate information with the drawings and/or specifications for the installation.
- ❑ Verify proper connection of the taps in accordance with the nameplate information.
- ❑ Check the clearance of all electrical connections. Verify all connections for tightness with a calibrated torque wrench.
- ❑ Visually check the core, frame, enclosure, conduits, raceways and conductors for proper ground bonding. In addition, refer to Grounding and Bonding on page 39.

Electrical Testing

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E. NOM-029-STPS-2011, or CSA Z462.
- This equipment must be installed and serviced only by qualified electrical personnel.
- Perform such work only after reading and understanding all of the instructions contained in this bulletin.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Always practice lock-out/tag-out procedures according to OSHA requirements.
- Carefully inspect your work area, and remove any tools and objects left inside the equipment.
- Replace all devices, doors, and covers before turning on power to this equipment.
- All instructions in this manual are written with the assumption that the customer has taken these measures before performing maintenance or testing.

Failure to follow these instructions will result in death or serious injury.

Refer to Maintenance on page 37 to perform the following pre-commissioning electrical testing:

- ❑ Measure contact resistance using a low resistance ohmmeter. Refer to Contact Resistance on page 39.
- ❑ Perform insulation resistance tests with an appropriate device. Refer to Insulation Resistance on page 39.
- ❑ Perform a turns ratio test on all taps and on the full winding voltages for each phase. Refer to Turns Ratio on page 39.
- ❑ Measure and record the winding resistances on larger transformers (>500 kVA). Refer to Winding Resistance on page 39.

Section 5—Operation

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E, NOM-029-STPS-2011, or CSA Z462.
- This equipment must be installed and serviced only by qualified electrical personnel.
- Perform such work only after reading and understanding all of the instructions contained in this bulletin.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Before performing visual inspections, tests, or maintenance on this equipment, disconnect all sources of electric power. Assume all circuits are live until they are completely de-energized, tested, and tagged. Pay particular attention to the design of the power system. Consider all sources of power, including the possibility of backfeeding.
- Always practice lock-out/tag-out procedures according to OSHA requirements.
- Carefully inspect your work area, and remove any tools and objects left inside the equipment.
- Replace all devices, doors, and covers before turning on power to this equipment.
- All instructions in this manual are written with the assumption that the customer has taken these measures before performing maintenance or testing.

Failure to follow these instructions will result in death or serious injury.

Effects of Humidity

The standard dip and baked varnish process does not support the growth of fungus. The only concern when units are stored in high humidity areas is retaining the integrity of the insulation material. If units are properly maintained and cleaned at shut down prior to long periods of de-energization there should be no issue with fungus.

Humidity conditions are unimportant as long as the transformer is energized. However, follow the precautionary steps listed below if the transformer is de-energized, is allowed to cool to ambient temperature, and will exceed a shutdown of 12 hours (especially in high humidity conditions).

1. Place small strip heaters in the bottom of the unit shortly after shutdown to maintain the temperature of the unit a few degrees above that of the outside air.
2. Inspect the unit for evidence of moisture before returning it to service.
3. Check the insulation resistance. If evidence of moisture exists, or if the insulation resistance is less than 1 megohm, dry out the transformer by placing it in an oven or by blowing heated air over it.

Enclosure Temperature

The temperature rise on the enclosure exterior for ventilated transformers should not exceed 122°F (50°C), except as indicated in UL 1561.

Prior to Energizing the Transformers

1. Remove any temporary braces. See Figure 33.
2. Check bolted electrical connections. Refer to Making Electrical Connections on page 26 for a detailed check list.
3. Remove excess dirt accumulations from the transformer windings and insulators to permit free circulation of air and to guard against the possibility of insulation breakdowns. Refer to Cleaning on page 38 for a detailed check list.
4. Perform insulation resistance tests with an appropriate device. Refer to Insulation Resistance on page 39 for a detailed instructions.
5. Perform a visual and mechanical check of the transformer and its surrounding environment. Refer to Performing Visual and Mechanical Checks on page 37 for a detailed check list.

Figure 33: Removing Temporary Braces

Energizing the Transformer

1. Follow all safety precautions and requirements for PPE as outlined in NFPA 70E and any other applicable standards and/or codes.
   a. Immediately de-energize the transformer if there is any indication of arcing (visual or audible) at any time during the initial start-up.
   b. Investigate and correct the cause of the arcing before re-energizing the unit.
2. Investigate and correct sources of excessive noise. When energized, the transformer will make some audible noise. Excessive mechanical noise, hums or rattles may be an indication of improperly installed or tightened hardware or enclosure parts.
3. Measure and verify the primary and secondary phase-to-phase and phase-to-ground voltages for all windings.
   a. Where applicable, measure and verify phase-to-neutral voltages, as well.
   b. Record and save the values for future reference.

   NOTE: Phase-to-phase, phase-to-ground and phase-to-neutral measurements will verify that the transformer is functioning per the nameplate voltages.

   c. Measure phase-to-ground voltages.
   d. Record and save the values for future reference.

   NOTE: Phase-to-ground voltages will verify that the unit has been installed correctly.

© 1992–2015 Schneider Electric All Rights Reserved

4. Move one tap at a time, or verify that the jumper lands per the wiring diagram as shown on the nameplate. See Figure 31 on page 28.

   NOTE: Do not change taps while the transformer is energized.

   a. Adjust the transformer taps as necessary to match the actual voltage requirements.

   b. Ensure taps are cleaned of varnish or other insulating material.

5. Perform a phase rotation check with an appropriate device for loads that are phase sensitive (e.g., certain motor or drive applications).

   a. Follow the manufacturer's instructions for the device.

   b. Correct phase rotation errors before energizing the transformer.

Section 6—Maintenance

Performing Visual and Mechanical Checks

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Only qualified personnel should clean, inspect maintain and test transformers.
- Turn off power supplying this equipment before working on it.
- Disconnect and electrically isolate power to the transformer so that no accidental contact can be made with energized parts.
- Discharge all static charges held by coils.

Failure to follow these instructions will result in death or serious injury.

1. Perform a visual inspection of the transformer and its surrounding environment.
   a. Inspect the enclosure for any physical damage.
   b. Repair any damage, if possible.
   c. Provide guards to prevent future damage.
2. Record operational data while the transformer is still energized and in service.
3. De-energize the transformer prior to performing work on the unit.
   a. Follow all safety procedures to place the unit into an electrically safe condition.
   b. Remove the access covers. Inspect for:
   — dirt on insulating surfaces and at areas which tend to restrict air flow.
   — loose connections.
   — the condition of tap changers or terminal boards.
   — the general condition of the transformer.
4. Inspect the enclosure, transformer, terminals, terminal boards, and insulators for signs of overheating from internal or external sources. Check for voltage creepage over insulating surfaces, evident by tracing or carbonization.
5. Check for evidence of rusting, corrosion and paint deterioration. Repair any rust and corrosion where necessary.

Frequency

The frequency at which transformers should be inspected depends on operating conditions.

For clean, dry locations, annual inspections may be sufficient. However, for other locations, such as where the air is contaminated with dust or chemical fumes, an inspection at three- or six-month intervals may be required. Usually after the first few inspection periods, a definite schedule can be set up based on the transformer's existing conditions.

ENGLISH

Severe, Environmental or Special Events

- ❑ Perform routine inspections, maintenance, and testing after any severe electrical short circuit, ground fault, or environmental event (e.g., flooding) to determine the operational status of the transformer.
- ❑ Perform the inspections, maintenance and testing if the transformer has been out of service for an extended period of time. Place strip heaters to maintain the transformer temperature above ambient to prevent condensation from forming in the transformer during extended down time.

Cleaning

Connections and Contact Surfaces

A clean contact surface area is necessary, and terminals must be clean. Where the transformers are installed indoors or outdoors or in a harsh environment, the connections must be sealed with an approved electrical joint compound.

Apply the compound to exposed connections and the surface area before making a bolted connection.

Enclosures, Windings and Insulators

1. De-energize the transformer.
2. Follow the check list below to permit free circulation of air and to guard against insulation breakdowns and thermal performance issues:

- ❑ Clean the transformer enclosure, windings and insulators by vacuuming or by blowing clean, dry, compressed air or nitrogen. Be sure to wear appropriate personal protective equipment (PPE) when cleaning.

  NOTE: Vacuuming is the preferred first step for cleaning. Compressed air should have a dew point of -50°F (-45.5°C) or less, and a pressure at or below 25 psi.
- ❑ Clean lead supports, tap changers, terminals boards, bushings and other major insulating surfaces with lint-free rags or soft bristle brushes.

  NOTE: Do not use liquids, solvents or detergents, as they may deteriorate insulating materials.
- ❑ Carefully inspect and thoroughly clean the ventilation openings (ducts) and winding assemblies. Remove any blockages.
- ❑ Remove any trash and/or combustible materials from the area around the unit.

Performing Electrical Testing

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Only qualified personnel should clean, inspect maintain and test transformers.
- Turn off power supplying this equipment before working on it.
- Disconnect and electrically isolate power to the transformer so that no accidental contact can be made with energized parts.
- Discharge all static charges held by coils.

Failure to follow these instructions will result in death or serious injury.

Perform the following electrical tests during maintenance:

© 1992–2015 Schneider Electric All Rights Reserved

- ❑ Check all electrical contacts with a calibrated torque wrench.
- ❑ Verify proper spacing.
- ❑ Refer to the manufacturer's specifications for torque values.
- ❑ Check all external hardware for tightness.

Contact Resistance

- ❑ Use a low resistance ohmmeter to measure contact resistance.
  a. Compare values with similar connections looking for unusually high contact resistance points.
  b. Investigate any connections that may deviate from common values by more than 50% of the lowest values.
- ❑ An infrared scanning device may be used to look for abnormal temperatures at transformer contacts for energized units.

  NOTE: Take care to follow the manufacturer's procedures, as small errors in scanner operation can cause significant errors in detected temperatures.

Insulation Resistance

Insulation resistance checks may create a capacitive charge on a winding.

1. Ground each winding for at least one minute between tests to drain any static charge created during the test.
2. Perform insulation resistance tests with an appropriate device.
3. Test from winding-to-winding and winding-to-ground.
4. Record all test results for comparison for future readings.
   — Values are installation site dependent and not pre-set at the factory. All testing is compliant to NEMA ST-20.
   — Insulation resistance readings should be at least 1 megohm.
   — Lower readings may indicate the presence of moisture and require a drying procedure to correct.

Winding Resistance

On larger transformers (>500 kVA):

1. Measure the winding resistances and record for future reference.
2. Compare the results with the values obtained during the pre-commissioning checks. Readings should not vary by more than 5% with adjacent coils and the pre-commissioning checks.
3. Record the temperature at which these initial readings were taken.
   — Values are installation site dependent and not pre-set at the factory. All testing is compliant to NEMA ST-20.
4. Adjust the resistance values based on any differences in temperature between current readings and pre-commissioning values.

Grounding and Bonding

1. Check for proper values of resistance between the system ground lug (or point) and the transformer enclosure, core, frame and clamps.
2. Compare with pre-commissioning values, looking for trends that may indicate a compromise in the quality of the ground bond.

Turns Ratio

1. Perform a turns ratio test on all taps and on the full winding voltages for each phase. Significant changes may indicate a loss of winding continuity.
   a. Compare these values with those obtained during the pre-commissioning checks. Voltages between phases should not deviate by more than 0.5% from adjacent coils.
   b. Investigate abnormal readings found outside of this limit.
2. Verify input and output voltages are correct for the tap and output voltages expected. Investigate abnormal readings.

© 1992–2015 Schneider Electric All Rights Reserved

Sound Isolation Pads

Inspect the sound isolation pads for signs of physical deterioration.

Coil Cooling Ducts

1. Inspect all coil cooling ducts for any accumulation of dust, dirt or other obstructions.
2. Follow standard cleaning procedures to ensure proper air flow.

Terminals

Ensure terminals are in good working condition for the proper operation of transformers.

- ❏ Inspect terminals for alignment, tightness (see torque requirements), pressure, burns or corrosion. Investigate and correct any signs of damage.
- ❏ Repair minor pitting, as long as the plating on the terminal has not been compromised.

NOTE: Refer to UL 486A for torque values to be used with lug connection hardware.

Two nameplates are attached to each unit. See Figure 36. One on the front cover which is required by standards, the second nameplate is attached to the core and coil, providing installation information inside the unit. The second nameplate also carries a UR listing for the core and coil, allowing the enclosure to be removed and the device installed in the equipment.

Hazard Categories and Special Symbols

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates an imminently hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a potentially hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a potentially hazardous situation which, if not avoided, **can result in** minor or moderate injury.

NOTICE

NOTICE is used to address practices not related to physical injury. The safety alert symbol is not used with this signal word.

NOTE: Provides additional information to clarify or simplify a procedure.

Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

Introduction

This bulletin contains instructions for installing Square D™ brand I-Line™ circuit breaker panelboards. These panelboards are Underwriters Laboratories (cULus) listed and accept I-Line branch circuit breakers.

For technical support on the installation of this panelboard, contact the Schneider Electric at customer support 1-888-778-2733.

See the labels on the equipment for rating and safety information. Additional equipment labels are provided with this document.

Safety Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside the equipment.
- Always use a properly-rated voltage sensing device to confirm all power is off.
- Read and understand this entire instruction bulletin and the latest edition of the NEMA PB 1.1 standards publication included before installing, operating, or maintaining this equipment.
- Local codes vary, but are adopted and enforced to promote safe electrical installations. A permit may be needed to do electrical work, and some codes may require an inspection of the electrical work.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Installation

This section provides instructions for the following I-Line panelboard procedures:

- Interior Mounting into Square D Brand Enclosures, on page 9
- Neutral Bonding Strap Installation, on page 12
- I-Line Circuit Breaker Installation and Removal, on page 14
- Interior Trim Barrier Preparation, on page 18

Interior Mounting into Square D Brand Enclosures

A separate standards publication, titled “General Instructions for Proper Installation, Operation, and Maintenance of Panelboards Rated 600 Volts or Less” (NEMA PB1.1-2007), has been provided with this equipment. Familiarize yourself with the content of this document before proceeding with any of the following procedures.

If you did not receive a copy of this document, or if you have any questions regarding this equipment, contact your local distributor or Schneider Electric representative.

NOTICE

HAZARD OF EXCESSIVE HEAT DUE TO LOOSE CONNECTION

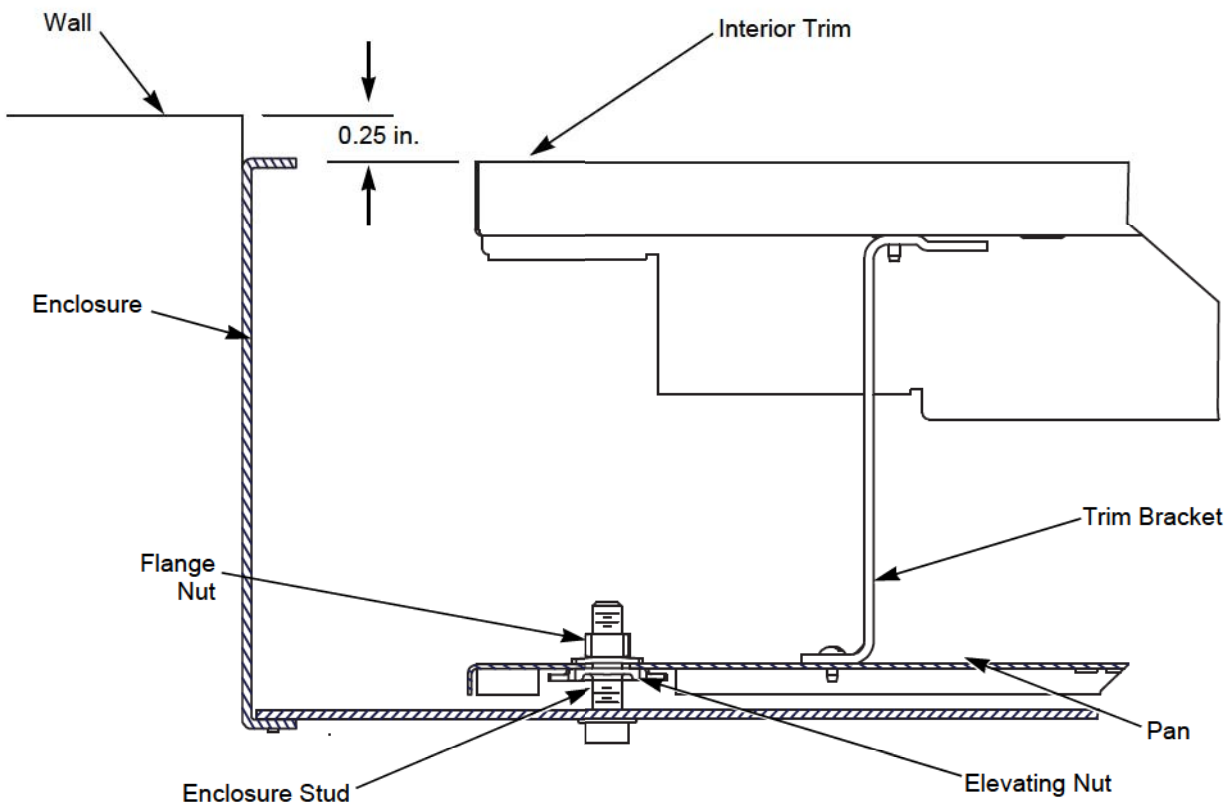
- Ensure all connections are properly tightened.
- Refer to the torque information label provided on the panelboard before tightening the connections.

Failure to follow these instructions can result in equipment damage.

To properly mount and install the I-Line panelboard enclosure, please refer to the NEMA PB 1.1-2007 standards publication, and follow the instructions below for either “Surface Mounting (Enclosure Mounted on Wall)” or “Flush Mounting (Enclosure Recessed in Wall).”

ENGLISH

Surface Mounting (Enclosure Mounted on Wall)



1. Mount the enclosure as instructed in the NEMA PB 1.1 standards publication.
2. Install one elevating nut on each enclosure stud.
3. Remove the interior trim from the trim brackets.
4. Install the interior as described below:
   a. Set the interior on the enclosure studs and secure with flange nuts (see Figure 1). Screwdriver blade may be inserted in elevating nut slot to facilitate adjustment.
   b. Adjust each elevating nut to maintain a maximum distance of 0.125 in. between the interior trim and the front/door assembly.
   c. Tighten the flange nuts against the pan.
   d. Remount the interior trim after wiring.
5. If used as service entrance equipment, neutral bonding is required (see “Neutral Bonding Strap Installation” on page 12).
6. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.

Flush Mounting (Enclosure Recessed in Wall)

1. Mount the enclosure as instructed in the NEMA PB 1.1-2007 standards publication.
2. Install one elevating nut on each enclosure stud.
3. Remove the interior trim from the trim brackets.
4. Install the interior as described below:
   a. Set the interior on the enclosure studs and secure with flange nuts (see Figure 1 on page 10). Screwdriver blade may be inserted in elevating nut slot to facilitate adjustment.
   b. Adjust each elevating nut to position the lip of the interior trim approximately 0.25 in. from the outside wall line.
   c. Tighten the flange nuts against the pan.
   d. Remount the interior trim after wiring.
5. If used as service entrance equipment, neutral bonding is required. See the “Neutral Bonding Strap Installation” instructions on page 12.
6. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.

Neutral Bonding Strap Installation

The neutral bonding strap should be used only when the panelboard is **installed** as service equipment.

To properly bond the neutral to the panelboard, follow the instructions for either “Standard Neutral Bonding Strap Installation” or “Neutral with Current Transformer Bonding Strap Installation” on pages 13 and 14, respectively.

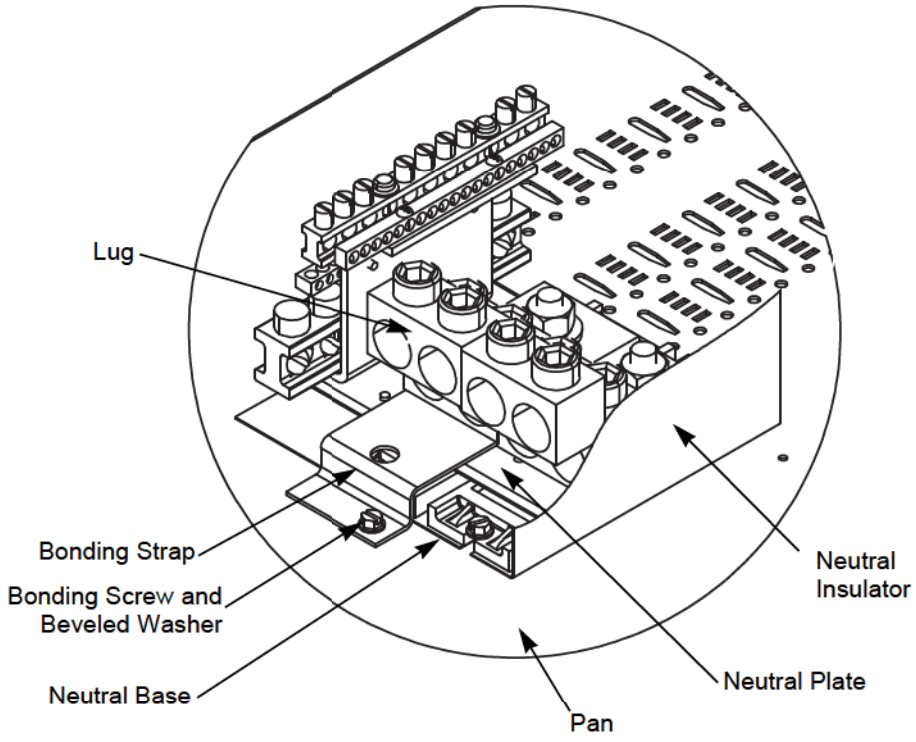
⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- Turn off all power supplying this equipment before working on or inside the equipment.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Always use a properly-rated voltage sensing device to confirm all power is off.
- The main bonding strap should be used only when the panelboard is installed as service equipment.
- Do not mix the mounting screws with the interior trim screws.

Failure to follow these instructions will result in death or serious injury.

NOTE: The bonding strap parts are found in the bag assembly provided with the interior.



ENGLISH

Standard Neutral Bonding Strap Installation

To install a neutral bonding strap on an I-Line panelboard, refer to Figure 2 and follow the instructions below.

1. Remove lug. Retain lug and fastening hardware.
2. Place bonding strap between neutral plate and lug, as shown.
3. Secure bonding strap to pan with bonding screw and beveled washer. Tighten the bonding screw to 65–75 lb-in (7.3–8.5 N•m).
4. Reinstall lug with the hardware retained in step 1. Tighten to 60–70 lb-in (6.8–7.9 N•m).

Figure 2: Standard Neutral Bonding Strap Installation

ENGLISH

Neutral with Current Transformer Bonding Strap Installation

To install a neutral bonding strap on an I-Line panelboard with a current transformer, refer to Current Transformer Neutral Bonding Installation Instructions, Schneider Electric document 80043-706-xx or 80043-789-xx, that is supplied with the current transformer neutral.

I-Line Circuit Breaker Installation and Removal

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly-rated voltage sensing device to confirm that all power is off.
- All unused spaces must be filled with blank fillers.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

I-Line Circuit Breaker Installation

Refer to Figure 3 on page 16 for the following instructions:

1. Turn off all power to the panelboard.
2. Remove the interior trim barrier.
3. Turn the circuit breaker off. Position the circuit breaker jaws against the bus bar stack so the guiding boss on the bottom of the circuit breaker is oriented towards the alignment groove in the bus insulator base, and the “fingers” of the circuit breaker mounting bracket fit into the keyslots in the pan.

   NOTE: Install the main circuit breaker adjacent to the main lugs.
4. Place a screwdriver through the rectangular hole in the circuit breaker mounting bracket and into the screwdriver slot in the mounting pan. Ratchet the circuit breaker firmly into the bus bar stack and align the retaining screw with the 0.219 in. (5.6 mm) mounting hole in the pan.
5. Tighten the retaining screw securely to prevent the circuit breaker from moving.

   NOTE: Ensure the retaining screw is tight, but do not tighten it enough to bend the mounting bracket.
6. **For main circuit breakers only:**
   Attach the “Main Breaker” label to the circuit breaker cover.
7. Reinstall the interior trim barrier.
8. Re-energize the panelboard.
9. Turn the circuit breaker on.

NOTE: I-Line circuit breakers are supplied with factory-applied joint compound on the plug-on connectors. The compound must not be removed because it contributes to the overall performance of the connection.

Whenever an I-Line circuit breaker is removed and reinstalled, the joint compound must be reapplied. A two-ounce container of compound especially formulated for I-Line plug-on connectors is available for purchase (catalog number PJC-7201).

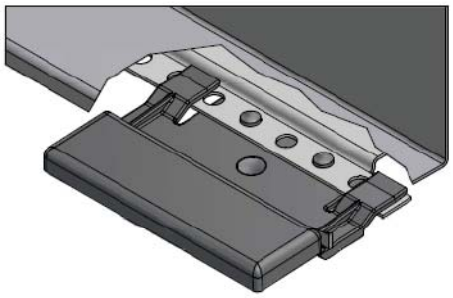
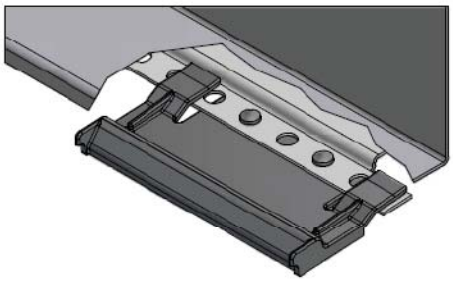
Figure 3: I-Line Circuit Breaker Installation and Removal



I-Line Circuit Breaker Removal

Refer to Figure 3 for the following instructions:



1. Turn off all power to the panelboard.
2. Turn the circuit breaker off.
3. Remove the interior trim barrier.
4. Loosen the retaining screw(s) in the circuit breaker mounting bracket until the screw(s) is completely removed from the 7/32 in. (5.6 mm) mounting hole in the mounting pan.
5. Place the screwdriver through the rectangular hole in the circuit breaker mounting bracket and into the screwdriver slot in the mounting pan. Ratchet the circuit breaker away from the bus bar stack.
6. Lift the circuit breaker away from the bus bars.
7. Install the blank fillers where the circuit breaker was removed, using Table 1 on page 18 as reference.
8. Secure the blank filler extensions to the interior trim barrier (HCPSU, HCP, and HCRU panelboards only), using Table 1 on page 18 for reference. Mount the extension over the mounting bracket in the deadfront as shown in Figure 4 on page 17.

9. Reinstall the interior trim barrier.
10. Re-energize the panelboard.

Circuit Breaker Reset Instructions

If the circuit breaker is tripped, the handle will be at the mid-position between ON and OFF. To reset the circuit breaker, push the handle to the OFF position, then to the ON position.

Interior Trim Barrier Preparation

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Before energizing the panelboard, all unused spaces must be filled with blank fillers.
- Replace all devices, doors, and covers before energizing this equipment.

Failure to follow these instructions will result in death or serious injury.

NOTICE

RISK OF IMPROPER ASSEMBLY

- Do not disassemble the I-Line Bus Stack Assembly.
- If maintenance is required, contact Schneider Electric.

Failure to follow these instructions can result in severe equipment damage and will void the warranty.

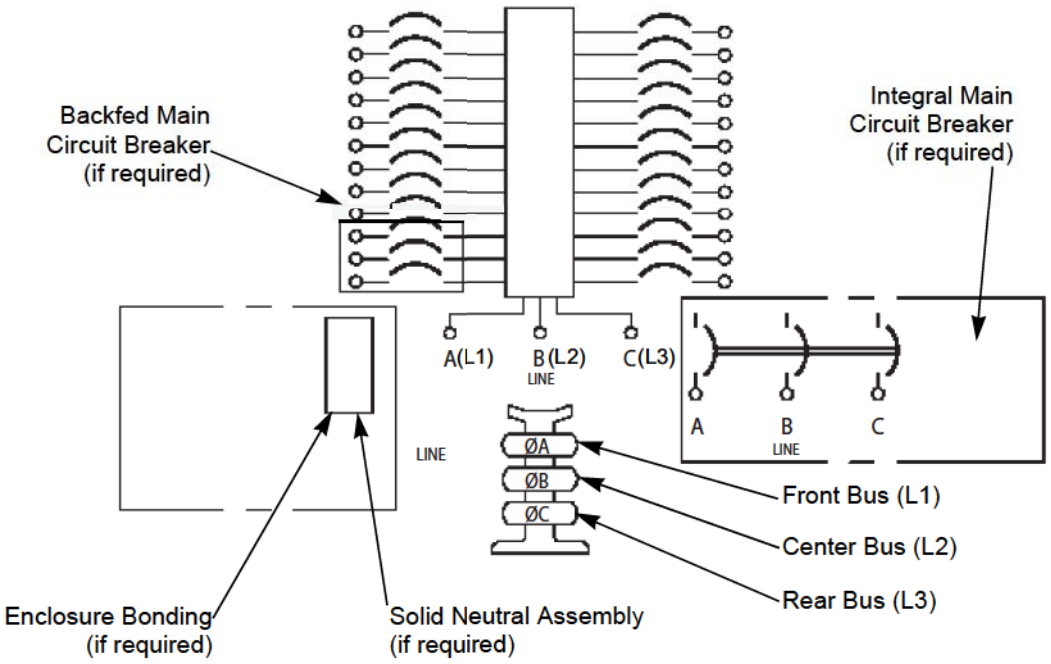
1 Additional information is provided on the panelboard. See the main circuit breaker rating, if used.

2 Unless otherwise specified.

3 Requires use of solid neutral assembly. See panelboard.



4 For grounded “B” phase system.

5 For use in Canada only.

6 When wiring for delta systems, phases “A” and “C” must be 120 V to neutral, with phase “B” 208 V to neutral. Connect only circuit breakers rated 240 V AC minimum, not 120 V or 120/240 V to “B” phase.

ENGLISH

Figure 6: Main Lugs / Main Circuit Breaker Wiring Diagram

NOTE: For 1Ø systems, the center bus is not used.

NOTE: Branch connections phasing is determined by the circuit breaker selected. See the latest catalog or the Digest for circuit breaker selection.

NOTE: Assure that the circuit breaker voltage rating is appropriate for the system. With the selection of proper units, any of the listed voltage systems can be used.

Panelboard Ratings

Refer to NEC section 110-22, 2011 Edition and CEC rule 12-014, 2002 Edition for more information. The series rated system label is located in the bag assembly. Short circuit tests are conducted at 100–105% of the maximum panelboard voltage. Interiors with CE mark meet IEC 61439-1 and IEC 61439-2.

Additional Short Circuit Current Ratings

Square D I-Line plug-on lugs installed in this panelboard and protected by indicated Square D circuit breakers are suitable for use where the available short circuit current is not greater than that shown in the following table. The short circuit current rating cannot exceed the rating marked on the protecting circuit breaker. The protecting circuit breakers may be the main, or if plugged onto the same I-Line bus stack, may be downstream from the plug-on lugs.

CE Marking

Interiors with the "CE" mark meet the IEC 61439-1 and IEC 61439-2 standards. Main Lug interiors with the "CE" mark have been tested to withstand 42,000 RMS symmetrical amperes for 30 cycles. Only IEC rated circuit breakers may be used with "CE" marked interiors and the short circuit rating of the interior is limited to the lowest IEC rated branch breaker unless series rated with an IEC rated main breaker in Table 4. (See Digest for details)

Equipment Ground Bar Kits

Equipment ground bar kits, suitable for copper or aluminum wire, meet the grounding needs of I-Line panelboards. Select the required kit according to the interior catalog number. Kits can be field installed.

Table 7: Equipment Ground Bar Kits Specifications

2 Copper bars suitable for 60° C or 75° C Copper conductors.

NOTE: Ground bar mounting locations are identified by the ground symbol ⏚ stamped into the back wall of the enclosure.

Mechanical Interlock Kits

Kits can be field installed.

1 Always ensure compression lugs are installed in panelboards that will provide wire bending space in accordance with NEC Article 312.6, 2011 Edition.

2 Unless otherwise specified, wire sizes apply to both aluminum and copper conductors.

3 When this lug is installed on a vertically mounted main circuit breaker, in an HCP interior, add box extension HC-4212-DEX (F or S) to the end of that enclosure.

4 Use crimp tools in accordance with instructions that are provided within each lug kit.

5 Always ensure compression lugs are installed in panelboards that will provide wire bending space in accordance with NEC Article 312.6, 2011 Edition. I-LINE panelboards with a Type 1 enclosure require a 5.0 in. extended width box when the branch breakers use these lugs (these compression lugs may not be used in weatherproof enclosures). Contact your local Schneider Electric representative for assistance.

6 This lug is only allowed in HCP/HCPSU panelboards with Type 1 enclosures with a 5.0 in. wide side extension.

7 For L-frame circuit breakers only.

HAZARD CATEGORIES AND SPECIAL SYMBOLS

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to potential personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates an imminently hazardous situation which, if not avoided, will result in death or serious injury.

⚠ WARNING

WARNING indicates a potentially hazardous situation which, if not avoided, can result in death or serious injury.

⚠ CAUTION

CAUTION indicates a potentially hazardous situation which, if not avoided, can result in minor or moderate injury.

CAUTION

CAUTION, used without the safety alert symbol, indicates a potentially hazardous situation which, if not avoided, can result in property damage.

Provides additional information to clarify or simplify a procedure.

PLEASE NOTE

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

Introduction

This bulletin contains instructions for installing Square D® brand NF and NFOM circuit breaker panelboards. These panelboards are Underwriters Laboratories (cULus) listed and accept ECB, EDB, EGB, and EJB branch circuit breakers.

For technical support on the installation of this panelboard, contact the Square D/Schneider Electric Customer Information Center at 1-888-SquareD (1-888-778-2733).

See the labels on the equipment for rating and safety information. Additional equipment labels are provided with this document.

Safety Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Read and understand this entire instruction bulletin and the included NEMA PB 1.1 standards publication before installing, operating, or maintaining this equipment.
- Local codes vary, but are adopted and enforced to promote safe electrical installations. A permit may be needed to do electrical work, and some codes may require an inspection of the electrical work.
- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside the equipment.
- Always use a properly-rated voltage sensing device to confirm all power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Installation

This section provides instructions for the following NF/NFOM panelboard procedures:

- “Interior Mounting for Square D Brand Enclosures” on page 8
- “Neutral Bonding Strap Installation” on page 11
- “ECB, EDB, EGB, and EJB Circuit Breaker Installation and Removal” on page 15
- “Circuit Breaker Reset Instructions” on page 17
- “Interior Trim Preparation” on page 18

Interior Mounting for Square D Brand Enclosures

A separate standards publication, titled “General Instructions for Proper Installation, Operation, and Maintenance of Panelboards Rated 600 Volts or Less” (NEMA PB1.1), has been provided with this equipment. Familiarize yourself with the content of this document before proceeding with any of the following procedures.

If you did not receive a copy of this document, or if you have any questions regarding this equipment, contact your local distributor or Schneider Electric representative.

CAUTION

HAZARD OF EQUIPMENT DAMAGE

- Ensure all connections are properly tightened.
- Refer to the torque information label provided on the panelboard before tightening the connections.

Failure to follow these instructions can result in equipment damage.

To properly mount and install the NF/NFOM panelboard interior, please refer to the NEMA PB 1.1 standards publication, and follow the instructions below for either “Surface Mounting (Enclosure Mounted on Wall)” or “Flush Mounting (Enclosure Recessed in Wall).”

ENGLISH

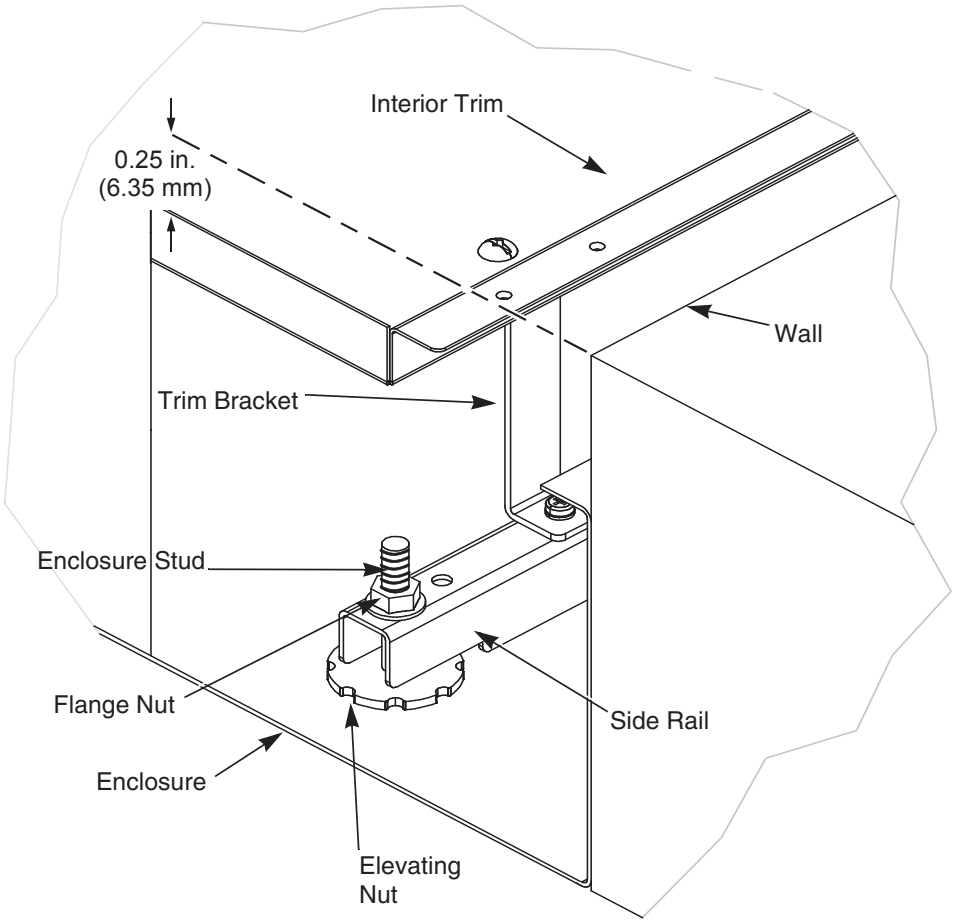
Surface Mounting (Enclosure Mounted on Wall)

1. Mount the enclosure as instructed in the NEMA PB 1.1 standards publication.
2. Remove the interior trim from the trim brackets.
3. Install the interior as described below:
   a. Thread the provided elevating nuts on the enclosure studs.
   b. Set the interior on the enclosure studs. (See Figure 1 on page 10).
   c. Tighten the flange nuts against the interior side rails until the rails are against the back of the enclosure.
   d. Remount the interior trim after wiring.
4. If used as service entrance equipment, neutral bonding is required. See the “Neutral Bonding Strap Installation” instructions on page 11.
5. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.



Flush Mounting (Enclosure Recessed in Wall)

1. Mount the enclosure as instructed in the NEMA PB 1.1 standards publication.
2. Remove the interior trim from the trim brackets.
3. Install the interior as described below:
   a. Thread the provided elevating nuts on the enclosure studs.
   b. Set the interior on the enclosure studs (see Figure 1 on page 10). Place the flange nuts onto the enclosure studs, but do not tighten.
   c. Adjust the elevating nuts so that the lip of the interior trim is approximately 0.25 inches (6.35 mm) from wall line.
   d. Tighten the flange nuts against the side rails.
   e. Remount the interior trim after wiring.
4. If used as service entrance equipment, neutral bonding is required. See the “Neutral Bonding Strap Installation” instructions on page 11.
5. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.

Neutral Bonding Strap Installation

The neutral bonding strap should be used only when the panelboard is **installed** as service equipment.

To properly bond the neutral to the panelboard, follow the instructions for either “125 A or 250 A Maximum NF Panelboards”, “400 A or 600 A Maximum NF Panelboards”, or “800 A Maximum NF Panelboards” below, and on pages 12–14.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Turn off all power supplying this equipment before working on or inside the equipment.
- The main bonding strap should be used only when the panelboard is installed as service equipment.
- Do not mix the mounting screws with the interior trim screws.

Failure to follow these instructions will result in death or serious injury.

NOTE: The bonding strap parts are found in the bag assembly provided with the interior.

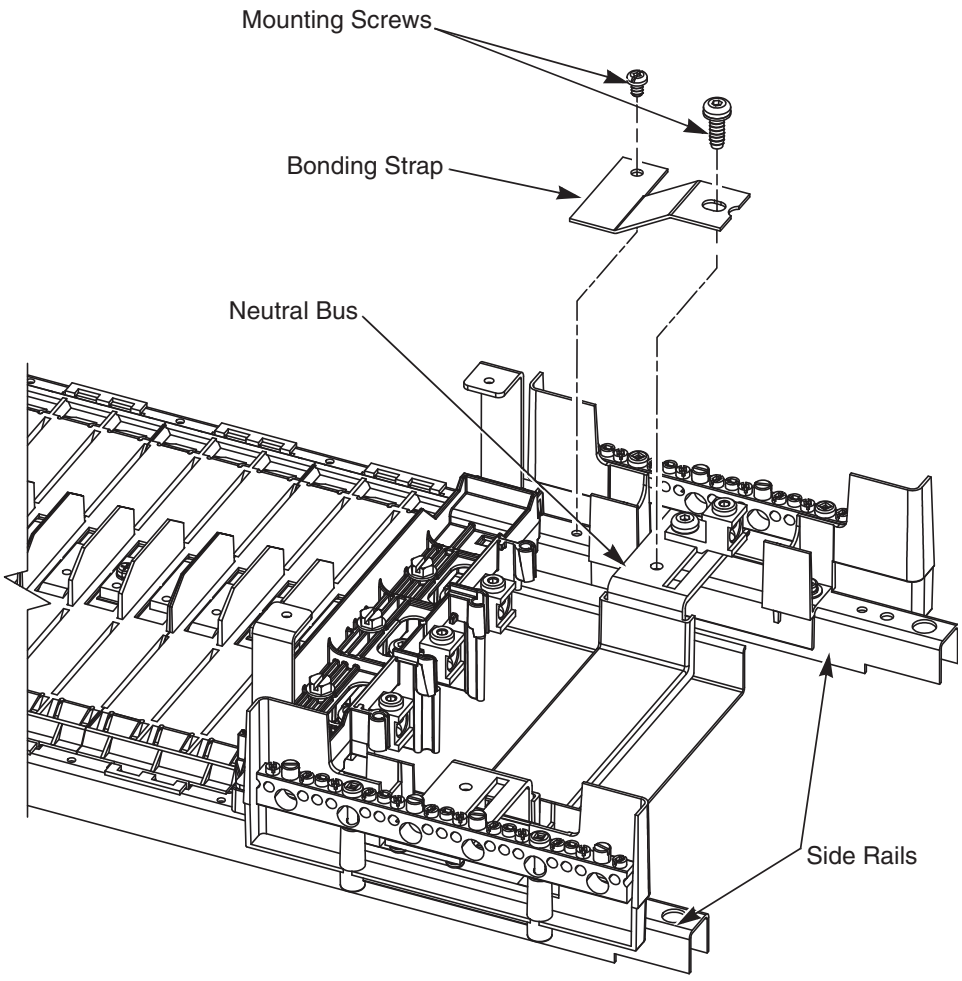
125 A or 250 A Maximum NF Panelboards

To install a neutral bonding strap on a 125 A or 250 A maximum NF panelboard, refer to Figure 2 and follow the instructions below.



1. Align the bonding strap on the side rail, as pictured.

   NOTE: For some applications, it may be necessary to remove the lug (not pictured) before installing the bonding strap.

2. Insert the two mounting screws, as pictured. Tighten the 10-32 screw to 10–12 lb-in (1.1–1.4 N•m) and the 1/4-20 screw to 25–30 lb-in (2.8–3.4 N•m).

   NOTE: If the lug was removed in Step 1, reinstall it on top of the bonding strap. Use the 1/4-20 x 3/4 in. mounting screw. Lug mounting screws are provided in the bonding strap bag assembly.

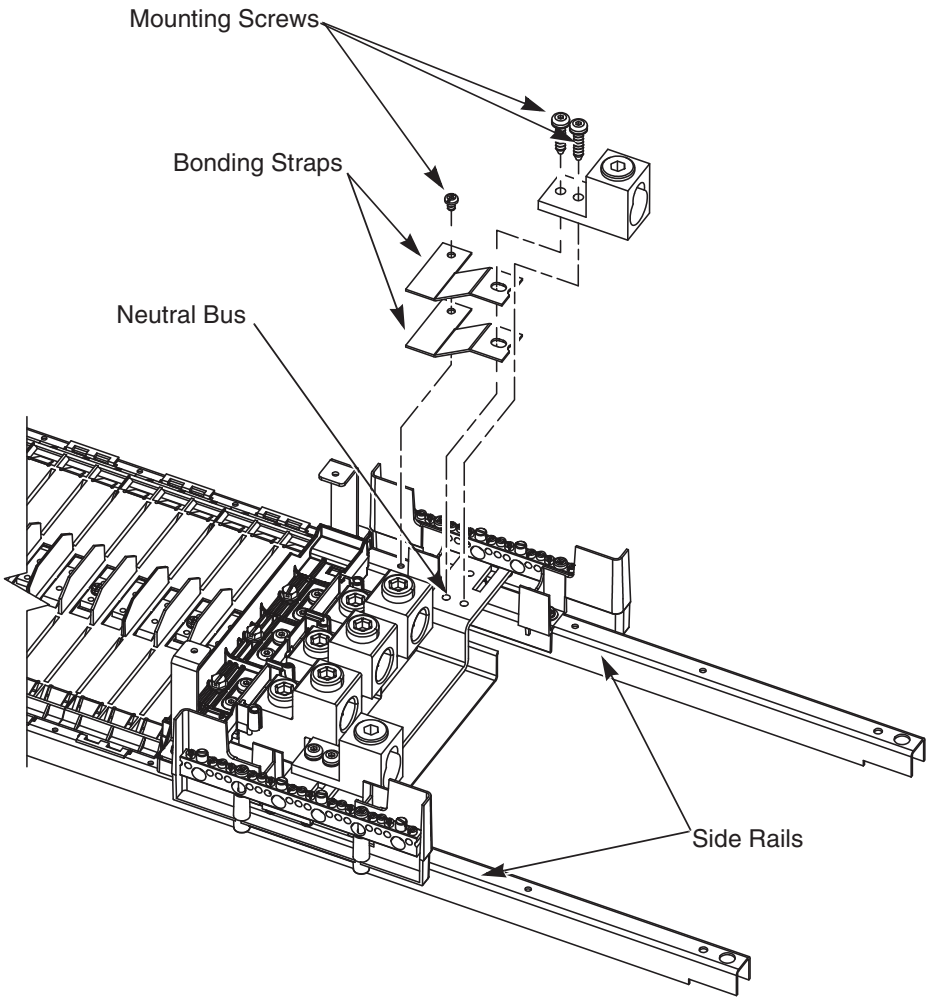
400 A or 600 A Maximum NF Panelboards

To install a neutral bonding strap on a 400 A or 600 A maximum NF panelboard, refer to Figure 3 and follow the instructions below.



1. Align the two bonding straps on the side rail, as pictured.

   NOTE: For some applications, it may be necessary to remove the lug before installing the bonding strap.

2. Insert the three mounting screws, as pictured. Tighten the 10-32 screw to 10–12 lb-in (1.1–1.4 N•m) and the two 1/4-20 screws to 60–65 lb-in (6.8–7.3 N•m).

   NOTE: If the lug was removed in Step 1 above, reinstall it on top of the bonding strap. Use the 1/4-20 x 1 1/8 in. mounting screws. Lug mounting screws are provided in the bonding strap bag assembly.

800 A Maximum NF Panelboards

To install a neutral bonding strap on an 800 A maximum NF panelboard, refer to Figure 4 and follow the instructions below.

1. Align the two bonding straps on the side rail, as pictured.
2. Insert the two mounting screws, as pictured. Tighten the 10-32 screw to 10–12 lb-in (1.1–1.4 N•m) and the 1/4-20 screw to 60–65 lb-in (6.8–7.3 N•m).

ECB, EDB, EGB, and EJB Circuit Breaker Installation and Removal

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly-rated voltage sensing device to confirm that all power is off.
- All unused spaces must be filled with blank fillers.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

ECB, EDB, EGB, and EJB Circuit Breaker Installation

Refer to Figure 5 on page 16 for the following instructions:

1. Turn off all power to the panelboard.
2. Turn the breaker off.
3. Remove the interior trim.
4. With the bolt-on connector end of the circuit breaker slightly elevated, insert the mounting foot into the slot in the phase cover.
5. Rotate the breaker down and back until the captive screw(s) align with the tapped holes in the breaker connectors.
6. Engage the screws into the branch connector hole and tighten it to 20–30 lb-in (2.3–3.4 N•m).
7. Install the load wire.
8. Reinstall the interior trim.

ECB, EDB, EGB, and EJB Circuit Breaker Removal

Refer to Figure 5 on page 16 for the following instructions:

1. Turn off all power to the panelboard.
2. Remove the interior trim.
3. Turn the breaker off.
4. Remove the load wire.
5. Loosen the screw(s) in the breaker connector and lift the breaker off of the panelboard.
6. Reinstall the interior trim.

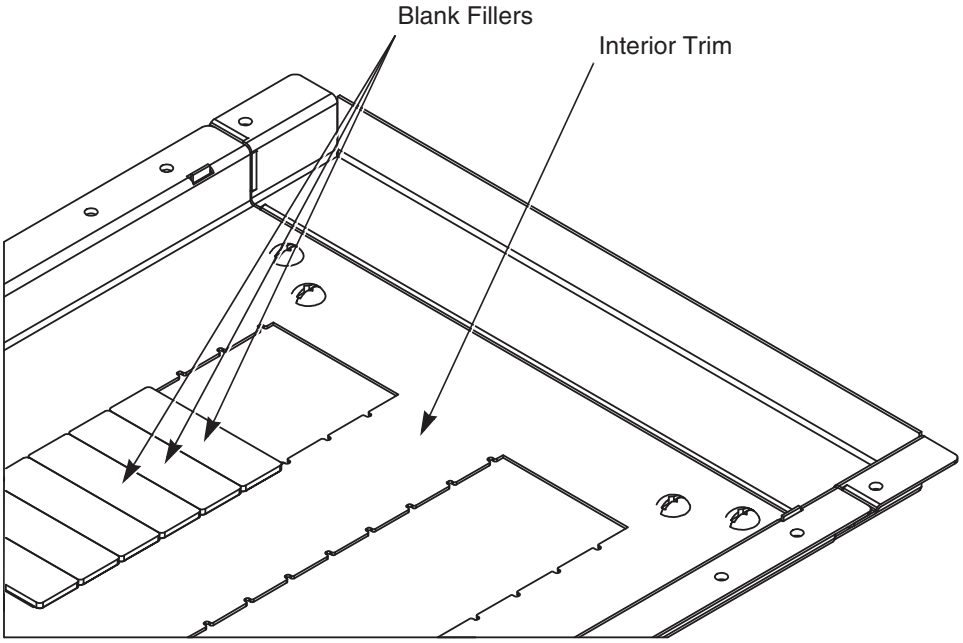
Interior Trim Preparation



⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Before energizing the panelboard, all unused spaces must be filled with blank fillers.
- Replace all devices, doors, and covers before energizing this equipment.

Failure to follow this instruction will result in death or serious injury.

Short Circuit Current Rating for Main Lug Interiors with Sub-Feed or Feed-Through Lugs

Main lug interiors equipped with sub-feed or feed-through lugs, where the device feeding the interior is unknown or not a Square D device, are rated to 25,000 RMS symmetrical amperes at 600Y/347 Vac maximum for three cycles. Use of one of the Square D circuit breakers of the correct ampere rating, listed as main circuit breakers on page 19, ahead of these lugs will result in a rating equal to that of the circuit breaker.

CAUTION

HAZARD OF EQUIPMENT DAMAGE

Use only one wire per phase for incoming circuit breaker connections when the integral LH main circuit breaker is upstream of the feed-through lugs.

Failure to follow these instructions can result in equipment damage.

CE Marking

Interiors with the “CE” mark meet the IEC 60439-1 standard.

Hazard Categories and Special Symbols

Read these instructions carefully and look at the equipment to become familiar with the device before trying to install, operate, service, or maintain it. The following special messages may appear throughout this bulletin or on the equipment to warn of potential hazards or to call attention to information that clarifies or simplifies a procedure.

The addition of either symbol to a “Danger” or “Warning” safety label indicates that an electrical hazard exists which will result in personal injury if the instructions are not followed.

This is the safety alert symbol. It is used to alert you to personal injury hazards. Obey all safety messages that follow this symbol to avoid possible injury or death.

⚠ DANGER

DANGER indicates an imminently hazardous situation which, if not avoided, **will result in** death or serious injury.

⚠ WARNING

WARNING indicates a potentially hazardous situation which, if not avoided, **can result in** death or serious injury.

⚠ CAUTION

CAUTION indicates a potentially hazardous situation which, if not avoided, **can result in** minor or moderate injury.

NOTICE

NOTICE is used to address practices not related to physical injury. The safety alert symbol is not used with this signal word.

NOTE: Provides additional information to clarify or simplify a procedure.

Please Note

Electrical equipment should be installed, operated, serviced, and maintained only by qualified personnel. No responsibility is assumed by Schneider Electric for any consequences arising out of the use of this material.

Introduction

This bulletin contains instructions for installing Square D™ brand NQ circuit breaker panelboards and QONQ load centers. These panelboards and load centers are Underwriters Laboratories (cULus) listed and accept QO™ and QOB branch circuit breakers.

For technical support on the installation of this panelboard, contact the Square D/Schneider Electric Customer Information Center at (1-888-778-2733).

See the labels on the equipment for rating and safety information. Additional equipment labels are provided with this document.

Safety Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462 or NOM-029-STPS.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn OFF all power supplying this equipment before working on or inside the equipment.
- Always use a properly-rated voltage sensing device to confirm all power is OFF.
- Read and understand this entire instruction bulletin and the included NEMA PB 1.1 standards publication before installing, operating, or maintaining this equipment.
- Local codes vary, but are adopted and enforced to promote safe electrical installations. A permit may be needed to do electrical work, and some codes may require an inspection of the electrical work.
- Replace all devices, doors and covers before turning ON power to this equipment.

Failure to follow these instructions will result in death or serious injury.

Installation

This section provides instructions for the following NQ panelboard and QONQ load center procedures:

- “Interior Mounting for Square D Brand Enclosures” on page 6
- “Neutral Bonding Strap/Cable Installation” on page 9
- “QO and QOB Circuit Breaker Installation and Removal” on page 12
- “Circuit Breaker Reset Instructions” on page 15
- “Interior Trim Preparation” on page 16

Interior Mounting for Square D Brand Enclosures

A separate standards publication, titled “General Instructions for Proper Installation, Operation, and Maintenance of Panelboards Rated 600 Volts or Less” (NEMA PB1.1), has been provided with this equipment. Familiarize yourself with the content of this document before proceeding with any of the following procedures.

If you did not receive a copy of this document, or if you have any questions regarding this equipment, contact your local distributor or Schneider Electric representative.

NOTICE

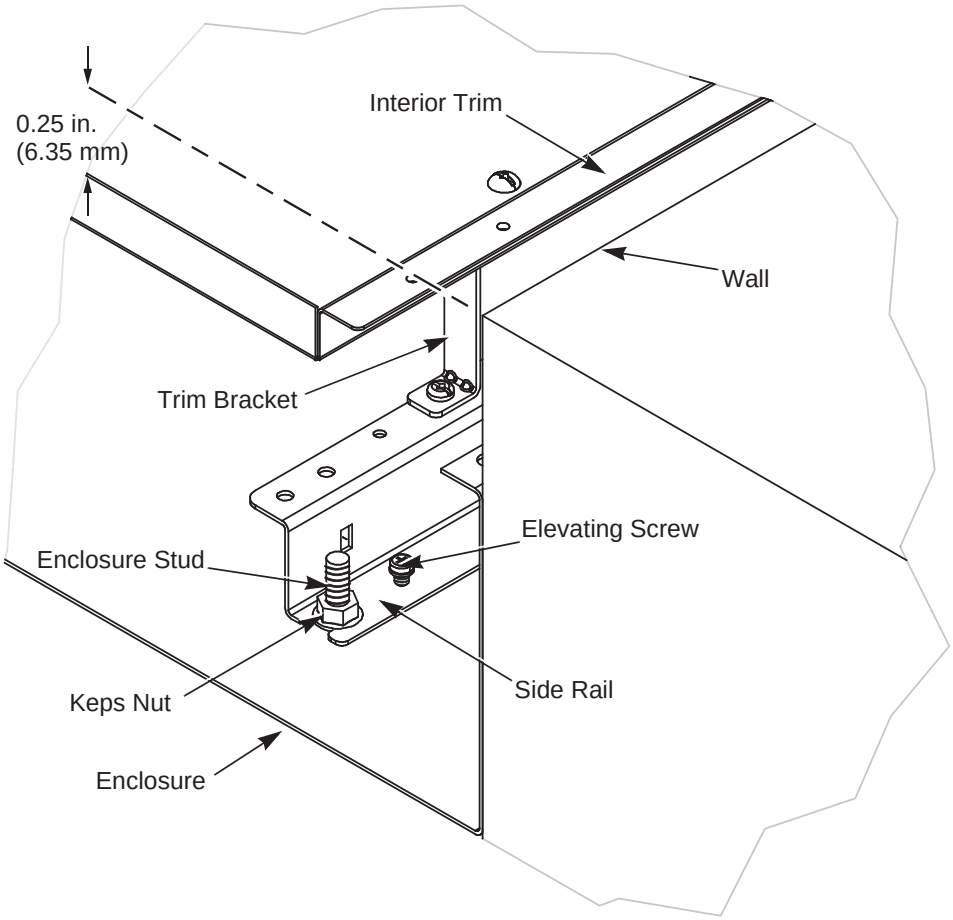
HAZARD OF EQUIPMENT DAMAGE DUE TO LOOSE CONNECTIONS

- Ensure all connections are properly tightened.
- Refer to the torque information label provided on the panelboard before tightening the connections.

Failure to follow these instructions can result in equipment damage.

To properly mount and install the NQ panelboard or QONQ load center interior, please refer to the NEMA PB 1.1 standards publication, and follow the instructions below for either ““Surface Mounting (Enclosure Mounted on Wall)” on page 7” or ““Flush Mounting (Enclosure Recessed in Wall)” on page 7.”

Surface Mounting (Enclosure Mounted on Wall)



1. Mount the enclosure as instructed in the NEMA PB 1.1 standards publication.
2. Remove the interior trim from the trim brackets.
3. Install the interior as described below:
   a. Set the interior on the enclosure studs. An elevating screw is not required (See Figure 1 on 8).
   b. Tighten the keps nuts against the interior side rails until the rails are against the back of the enclosure.
   c. Remount the interior trim after wiring.
4. If used as service entrance equipment, neutral bonding is required. See the “Neutral Bonding Strap/Cable Installation” instructions on page 9.
5. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.

Flush Mounting (Enclosure Recessed in Wall)

1. Mount the enclosure as instructed in the NEMA PB 1.1 standards publication.
2. Remove the interior trim from the trim brackets.
3. Install the interior as described below:
   a. Thread the (4) 10-32 x .875 in. self-tapping, elevating screws provided with the flush trim into the side rails.
   b. Set the interior on the enclosure studs (see Figure 1 on 8). Place the keps nuts onto the enclosure studs, but do not tighten.
   c. Adjust the screws so that the lip of the interior trim is approximately 0.25 inches (6.35 mm) from wall line.
   d. Tighten the keps nuts against the side rails.
   e. Remount the interior trim after wiring.
4. If used as service entrance equipment, neutral bonding is required. See the “Neutral Bonding Strap/Cable Installation” instructions on page 9.
5. Apply equipment labels (located in the bag assembly) as directed by the instructions on the back of the equipment label sheet.

Neutral Bonding Strap/Cable Installation

The neutral bonding strap/cable should be used only when the panelboard is **installed** as service entrance equipment.

To properly bond the neutral to the panelboard, follow the instructions for either “100 or 250 A Maximum NQ Panelboards” or “400 or 600 A Maximum NQ Panelboards and QONQ Load Centers” below and on page 11, respectively.

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462 or NOM-029-STPS.
- Turn OFF all power supplying this equipment before working on or inside the equipment.
- The main bonding strap/cable should be used only when the panelboard is installed as service entrance equipment.
- Do not mix the mounting screws with the interior trim screws.

Failure to follow these instructions will result in death or serious injury.

NOTE: The bonding strap/cable parts are found in the bag assembly provided with the interior.

100 or 250 A Maximum NQ Panelboards

To install a neutral bonding strap on a 100 or 250 A maximum NQ panelboard, refer to Figure 2 and follow the instructions below.

1. Align the bonding strap on the side rail, as pictured.

   NOTE: For some applications, it may be necessary to remove the lug (not pictured) before installing the bonding strap.

ENGLISH

2. Insert the two mounting screws, as pictured. Tighten the 10-32 screw to 10–12 lb-in (1.1–1.4 N•m) and the 1/4-20 to 25–30 lb-in (2.8–3.4 N•m).

   NOTE: If the lug was removed in Step 1 above, reinstall it on top of the bonding strap. Use the 1/4-20 x 11/16 in. mounting screw with feed-through lug, sub-feed lug, sub-feed breaker, or 200% neutral applications. Use the 1/4-20 x 7/8 in. lug mounting screw with 200% neutral on 225 A applications with feed-through lug, sub-feed lug, or sub-feed circuit breaker applications. Lug mounting screws are provided in the bonding strap bag assembly.

ENGLISH

400 or 600 A Maximum NQ Panelboards and QONQ Load Centers

To install a neutral bonding cable on a 400 or 600 A maximum NQ panelboard and QONQ load center, refer to Figure 3 and follow the instructions below.

1. Align the lug on the side rail mounting hole, as pictured.
2. Tighten the lug mounting screw against the side rail to 10–12 lb-in (1.1–1.4 N•m).
3. Align the bonding cable, as pictured, and insert it into the lug and neutral mounting holes.
4. Tighten both the lug wire binding screw and the neutral wire binding screw to 45–50 lb-in (5.1–5.6 N•m).

QO and QOB Circuit Breaker Installation and Removal

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462 or NOM-029-STPS.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn OFF all power supplying this equipment before working on or inside equipment.
- Always use a properly-rated voltage sensing device to confirm that all power is OFF.
- All unused spaces must be filled with blank fillers.
- Replace all devices, doors and covers before turning ON power to this equipment.

Failure to follow these instructions will result in death or serious injury.

QO and QOB Breaker Installation

Refer to Figure 4 on 14 for the following instructions:

1. Turn OFF all power to the panelboard.
2. Turn the breaker OFF.
3. Remove the interior trim.
4. Snap the wire terminal end of the circuit breaker onto the mounting rail.
5. Engage the branch connector.

   For QO Circuit Breakers:

   a. Push inward until the plug-on jaws fully engage the branch connector.

   For QOB Circuit Breakers:

   a. Push inward until the breaker connector is centered on the branch connector mounting hole. Engage the screw into the branch connector hole and tighten it to the torque values shown on the interior wiring and torque diagram.

6. Install the load wire.
7. Reinstall the interior trim.

QO and QOB Breaker Removal

Refer to Figure 4 on 14 for the following instructions:

1. Turn OFF all power to the panelboard.
2. Remove the interior trim.
3. Remove the load wire.
4. Disengage the branch connector.

   For QO Circuit Breakers:

   a. Pull outward until the plug-on jaws fully disengage the branch connector.

   For QOB Circuit Breakers:

   a. Loosen the screw in the breaker connector and pull the breaker off of the branch connector.

ENGLISH

5. Snap the wire terminal end of the circuit breaker off of the mounting rail.
6. Reinstall the interior trim.

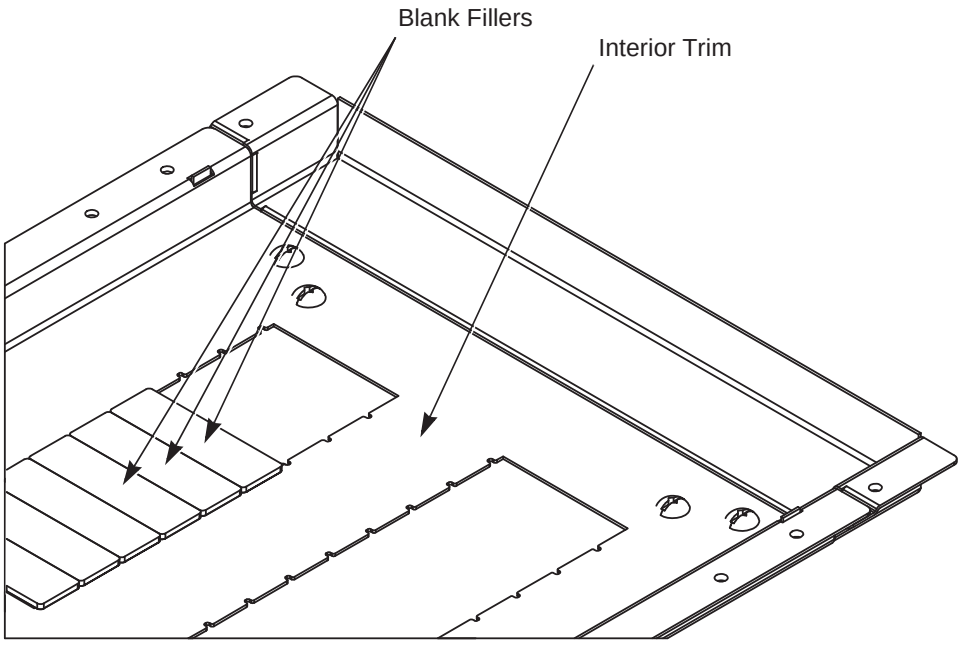
Interior Trim Preparation



⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462 or NOM-029-STPS.
- Before energizing the panelboard, all unused spaces must be filled with blank fillers.
- Replace all devices, doors, and covers before energizing this equipment.

Failure to follow this instruction will result in death or serious injury.

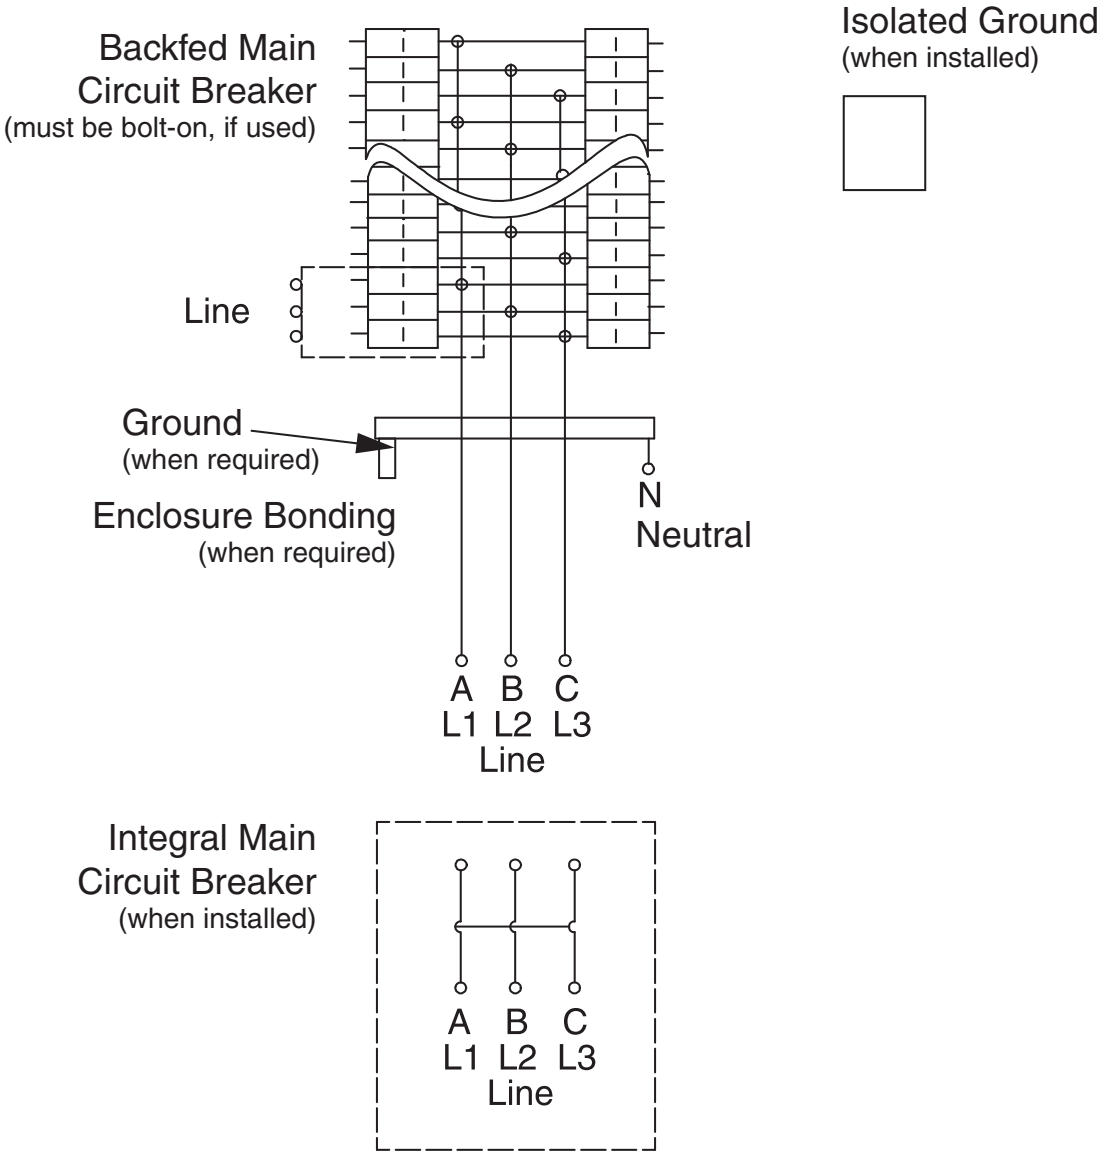
1 Additional information is provided on the panelboard. See the main circuit breaker rating, if used.

2 For this system, the neutral is not used and only circuit breakers rated 240 V AC minimum should be used. Do not use circuit breakers rated 120 V or 120/240 V AC.



3 For a grounded “B” phase system, only circuit breakers rated 240 V AC minimum should be used. Do not use circuit breakers rated 120 V or 120/240 V AC.

4 When wiring for a delta system, phases “A” and “C” must be 120 V to neutral, phase “B” 208 V to neutral. Connect only circuit breakers rated 240 V AC minimum. Do not use circuit breakers rated 120 V or 120/240 V to “B” phase.

1 For shown circuit breakers rated less than this maximum voltage, the indicated short circuit current rating also applies, but at the voltage rating of the circuit breaker.

2 Short circuit tests are conducted at 100–105% of the maximum rated voltage of the panelboard.

3 Suffixes HID, SWD, and SWN may also be applied to the applicable branch circuit breakers shown above. Suffix SWN may **not** be applied in combination with LC main breakers.

4 Where QO (B) circuit breakers are shown above, QO (B) H, QO (B) VH, and QH (B) circuit breakers may also be used.

5 Where QO (B) GFI circuit breakers are shown above, QO (B) EPD and/or QO (B) EPE circuit breakers may also be used. QO-EPE only comes in 3 pole construction.

6 Where QO (B) AFI circuit breakers are shown above, QO (B) CAFI circuit breakers may also be used.

7 To achieve selective coordination, the rating of the DJ main circuit breaker must be at least two times greater than the ampere rating of any branch circuit breaker.

Table 4: Short Circuit Current Rating[1] for Main Lug Interiors with Sub-Feed or Feed-Through Lugs

Maximum System Voltage AC	Maximum Current Rating	Branch Circuits	Application	Adder[2]	Maximum Short Circuit Current Rating[3]
240	100	18, 30	SFL and FTL	—	10,000
	225	30, 42, 54, 72, 84	SFL	6 inches (152.4 mm)	
		42	FTL	—	
		30, 54, 72, 84		6 inches (152.4 mm)	
	400	30, 42, 54, 72, 84	SFL	—	25,000
		30, 84	FTL	—	
		42, 54, 72		6 inches (152.4 mm)	
	600	30, 42, 54, 72, 84	FTL	12 inches (304.8 mm)	

1 This rating applies to main lug interiors, equipped with sub-feed or feed-through lugs, where the device feeding the interior is unknown or not a Square D brand device. Use of a Square D brand main circuit breaker ahead of these lugs will result in a rating equal to the rating of the breaker. Short circuit tests are conducted at 100–105% of the maximum rated voltage of the panelboard.

2 The adder is the additional length of the enclosure.

3 RMS symmetrical amperes, for three cycles.

CE Marking

Interiors with the "CE" mark meet the IEC 61439-1 and IEC 61439-2 standards.
Main lug interiors with the "CE" mark have been tested to withstand 10,000 RMS symmetrical amperes for 30 cycles.
Interiors with the "CE" mark are only approved for use with QOXD or QOBXD branch circuit breakers which carry the "CE" mark.

Appendix 2: Accessory Kits

An assortment of field-installable accessory kits are available for NQ panelboards:

- Equipment Ground Bar Kits
- Oversized Lug Kits for 100–250 A Panelboards
- Sub-Feed Lug Kits for 100–400 A Panelboards
- Main Lug Kits
  - — Mechanical Lug Kits—Aluminum
  - — Mechanical Lug Kits—Copper
  - — Versa-Crimp® Compression Lug Kits—Aluminum
  - — Versa-Crimp Compression Lug Kits—Copper

Equipment Ground Bar Kits

Equipment ground bar kits, suitable for copper or aluminum wire, meet the grounding needs of NQ panelboards and QONQ load centers.

1 Aluminum bars suitable for 60° C or 75° C Copper or Aluminum conductors.

2 Copper bars suitable for 60° C or 75° C Copper conductors.

NOTE: Ground bar mounting locations are identified by the ground symbol ⏚ stamped into the backwall of the enclosure.

Foreword

This publication is a guide of practical information containing instructions for the proper installation, operation, and maintenance of panelboards rated 600 volts or less.

These instructions do not purport to cover all details or variations in equipment, nor to provide for every possible contingency regarding installation, operation, or maintenance.

It is recommended that work described in this set of instructions be performed only by qualified personnel familiar with the construction and operation of panelboards and that such work be performed only after reading this complete set of instructions. For specific information not covered by these instructions, you are urged to contact the manufacturer of the panelboard directly.

In the preparation of this standards publication input of users and other interested parties has been sought and evaluated. Inquiries, comments, and proposed or recommended revisions should be submitted to the concerned NEMA product section by contacting the following: These recommendations will be reviewed periodically and updated as necessary.

Publication PB 1.1- 2013 revises and supersedes PB 1.1-2007.

This standards publication was developed by the Panelboard and Distribution Board Product Group of the LVDE Section. Product Group approval of the standard does not necessarily imply that all Product Group members voted for its approval or participated in its development. At the time it was approved, the Product Group was composed of the following members:

Eaton Corporation.—Pittsburgh, PA
GE Industrial Solutions—Plainville, CT
Hubbell, Inc.—Orange, CT
Milbank Manufacturing Company—Kansas City, MO
Penn Panel & Box Company—Collingdale, PA
Reliance Controls Corporation—Racine, WI
Siemens Industry, Inc.—Norcross, GA

Section 1
SCOPE

This publication covers single panelboards or groups of panel units suitable for assembly in the form of single panelboards, including buses, and with or without switches or automatic overload protective devices (fuses or circuit breakers), or both. These units are used in the distribution of electricity at 600 volts and less with:

1600—ampere mains or less
1200—ampere branch circuits or less

Specifically excluded are live-front panelboards, panelboards employing cast enclosures for special service conditions, and panelboards designed primarily for residential and light commercial service equipment.

GENERAL

WARNING—HAZARDOUS VOLTAGES IN ELECTRICAL EQUIPMENT CAN CAUSE SEVERE PERSONAL INJURY OR DEATH. UNLESS OTHERWISE SPECIFIED, INSPECTION AND MAINTENANCE SHOULD ONLY BE PERFORMED ON PANELBOARDS AND EQUIPMENT TO WHICH POWER HAS BEEN TURNED OFF, DISCONNECTED AND ELECTRICALLY ISOLATED SO THAT NO ACCIDENTAL CONTACT CAN BE MADE WITH ENERGIZED PARTS. FOLLOW ALL MANUFACTURER'S WARNINGS AND INSTRUCTIONS.

Safety-related work practices, as described in NFPA 70E, should be followed at all times.
All requirements of the *National Electrical Code*® NFPA 70 should be followed.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE PANELBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE COMPONENTS DURING INSTALLATION OR MAINTENANCE.

3.1 SUCCESSFUL OPERATION OF PANELBOARDS

The successful operation of panelboards is dependent upon proper installation, operation, and maintenance. Neglecting fundamental installation and maintenance requirements may lead to personal injury, death, or damage to electrical equipment or other property.

3.2 QUALIFIED PERSONNEL

Installation, operation, and maintenance of panelboards should be conducted only by qualified personnel.

3.3 DEFINITION OF QUALIFIED PERSONNEL

For purposes of these guidelines, a qualified person is one who is familiar with the installation, construction, and operation of the equipment and the hazards involved. In addition, the person is:

3.3.1 Requirements

Knowledgeable of the requirements of the *National Electrical Code*® and of all other applicable codes, laws, and standards.

3.3.2 Established Safety Practices

Trained and authorized to test, energize, clear, ground, tag, and lockout circuits and equipment in accordance with established safety practices.

3.3.3 Protective Equipment

Trained in the proper care and use of protective equipment such as rubber gloves, hard hat, safety glasses or face shields, and flash resistant clothing in accordance with established safety practices.

3.3.4 First Aid

Trained in rendering first aid.

3.4 SUITABLE RATINGS

Verify that all equipment being installed has ratings suitable for the installation.

Section 4
INSTALLATION OF PANELBOARD CABINETS (BOXES)

4.1 INSTALLATION INSTRUCTIONS

Installation of the cabinet in a neat and workmanlike manner. Follow the manufacturer's installation instructions.

4.2 LOCATION IN BUILDING

Locate the cabinet so that it is readily accessible and not exposed to physical damage.

4.3 FLAMMABLE MATERIAL

Locate the cabinet well away from flammable material.

4.4 UNUSUAL SERVICE CONDITIONS

Do not locate the cabinet where it will be exposed to ambient temperatures above 40°C (104°F), corrosive or explosive fumes, dust, vapors, dripping or standing water, abnormal vibration, mechanical shock, high humidity, tilting, or unusual operating conditions, unless the cabinet/panelboard combination has been designed and so identified by the manufacturer for these conditions.

4.5 INDOOR DAMP LOCATIONS

Locate or shield the cabinet so as to prevent moisture and water from entering and accumulating therein. Mount the cabinet so that there is at least 1/4 inch of air space between the cabinet and the wall or other supporting surface.

4.6 WET LOCATIONS

Cabinets should be specifically approved for wet locations. Mount the cabinet so that there is at least 1/4 inch of air space between the cabinet and the wall or other supporting surface.

4.7 CLEARANCE FROM CEILING

Do not locate the cabinet against a non-fireproof ceiling; allow a space of 3 feet between the ceiling and cabinet unless an adequate fireproof shield is provided.

4.8 SPACE AROUND THE CABINET

When selecting a location, provide sufficient access and working space around the cabinet (see Section 110.26 of the *National Electrical Code*®). The width of the working space in front of the panelboard should be at least 30 inches, or the width of the cabinet, whichever is greater, and this space should not be used as storage. The working space should have adequate lighting and a minimum head room of 6 feet 6 inches.

4.9 MOUNTING OF CABINET

The cabinet should be reliably secured to the mounting surface. Do not depend on wooden plugs driven into holes in masonry, concrete, plaster, or similar materials. (See Section 110.13 of the *National Electrical Code*®.)

© 2014 National Electrical Manufacturers Association

4.10 FLUSH MOUNTING IN WALL

In walls of concrete, tile, or other noncombustible material, install the cabinet so that its front edge will not set back more than 1/4 inch from the finished surface. In walls of wood or other combustible material, cabinets should be flush with or project beyond the finished surface. (See Section 312.3 of the *National Electrical Code*®.)

4.11 UNUSED OPENINGS IN CABINET

Effectively close unused openings in the cabinet to provide protection which is substantially equivalent to that afforded by the wall of the cabinet.

4.12 GROUNDING OF PANELBOARD CABINETS

Ground the cabinet as specified in Article 250 of the *National Electrical Code*®. When the cabinet contains service equipment, it is necessary to bond the cabinet to the grounded (neutral) service conductor.

© 2014 National Electrical Manufacturers Association

Section 5
INSTALLATION OF CONDUIT AND CONDUCTORS

5.1 CONDUITS INSTALLATION

Conduits should be installed so as to prevent moisture or water from entering and accumulating within the enclosure. Provision should be made to protect conductors from abrasion in accordance with Article 312 of the *National Electrical Code*®.

5.2 KNOCKOUTS REMOVAL

Knockouts should be removed as follows:

IMPORTANT—Remove knockouts, ONE AT A TIME, alternating INWARD and OUTWARD.

5.2.1 First Step—Remove Center Knockout

Remove center knockout INWARD.

5.2.1.1 Screwdriver Blade

Place screwdriver blade against point farthest from tie and strike INWARD (Figure 1). Bend back and forth to break tie.

5.2.2 Next Step—Remove Rings

Remove rings ONE AT A TIME without straining remaining rings.

5.2.2.1 Pry First Ring

Pry first ring OUTWARD with screwdriver midway between ties, using pliers flat against box under screwdriver (Figure 2). Bend ring sections OUTWARD with pliers, then back and forth to break ties (Figure 5-3).

5.2.2.2 Second Ring

Remove second ring INWARD by striking screwdriver (with blade against point midway between ties) then breaking ring sections inward and back and forth to break ties.

5.3 *NATIONAL ELECTRICAL CODE*®, ARTICLE 300

Refer to the *National Electrical Code*®, Article 300 for proper wiring methods. See 6.7 for making proper connections.

5.4 CONDUCTOR LENGTH

Keep conductor length to a minimum within the wiring gutter. Excessive conductor length will result in additional heating and may result in overheating. However, conductors should be long enough to reach the terminal location in a manner that avoids strain on the terminal.

5.5 EXERCISE CARE

Exercise care to maintain the largest practical bending radius of conductors; otherwise the insulation may be damaged and terminal connections may become loosened. Deflection of conductors shall comply with *NEC*® Section 312.6.

© 2014 National Electrical Manufacturers Association

5.6 *NATIONAL ELECTRICAL CODE*®, SECTION 725.136

Refer to the *National Electrical Code*®, Section 725.136 for the separation requirements for conductors of Class 2 and Class 3 remote-control, signaling and power-limited circuits.

Section 6
INSTALLATION OF PANELBOARD

6.1 PROPER STORAGE

Store the panelboard in a clean, dry place located so that mechanical damage from work personnel in the area is not likely to happen.

6.2 UNPACKING

Care should be exercised in unpacking the panelboard to prevent damage and loss of instruction materials and loose parts.

6.3 INSPECTION

Check for shipping damage and check to make sure that the panelboard is the correct one for installation in the cabinet.

6.4 CARE

Care should be taken to protect the panelboard internal parts from contamination during the installation process.

6.4.1 Cleaning

Clean the cabinet of all foreign materials. If parts at connection points are spattered with cement, plaster, paint, or other foreign material, remove the foreign materials with great care to avoid damage to the plating.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE PANELBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE PANELBOARD COMPONENTS DURING INSTALLATION OR MAINTENANCE.

6.5 MANUFACTURER'S INSTRUCTIONS

Carefully follow the manufacturer's instructions and labels.

6.6 INSTALLATION

6.6.1 Alignment Devices

Adjust the alignment devices where provided.

6.6.2 Panelboard

Install the panelboard, finalize its alignment, and tighten it securely in the cabinet.

6.6.3 Flange of Deadfront Shield

Unless otherwise instructed by the manufacturer, adjust the panelboard so that the flange of the deadfront shield is no more than 3/16 inch from (1) the front of the cabinet for surface mounting or (2) the surrounding wall surfaces for flush mounting.

© 2014 National Electrical Manufacturers Association

6.7 LINE AND BRANCH CONDUCTORS

Connect Line and Branch Conductors

6.7.1 Conductors

Use care in stripping insulation from conductors so as not to nick or ring the conductor. For aluminum, clean all oxide from the stripped portion and apply an antioxide compound.

6.7.1.1 Wiring Gutters

Distribute and arrange conductors neatly in the wiring gutters. (See Section 5.)

6.7.1.2 Types and Temperature Ratings

Care should be exercised to ensure that the types and temperature ratings of conductors being installed in the panelboard are suitable for use with the terminals, which have been provided.

6.7.1.3 Tighten All Terminals

Use the manufacturer's torque values. (See 7.1).

6.8 PANELBOARD GROUNDING AND BONDING

Ground the panelboard cabinet in accordance with 4.12. (See Section 408.40 of the *National Electrical Code*®.)

6.8.1 Equipment Grounding Conductors

Where separate equipment grounding conductors are used, prepare equipment grounding conductors in accordance with 6.7.1 and connect them to the equipment grounding terminal bar. Check to be sure that the terminal bar is securely bonded to the cabinet or panelboard frame and that it is not connected to the neutral bar except at service equipment (as permitted in Section 250.28 of the *National Electrical Code*®) or at separately derived systems (as permitted in Section 250.30 of the *National Electrical Code*®).

NOTE—An equipment grounding terminal bar is not always required. For example, when a properly installed metallic raceway is used as the equipment grounding path or when the grounded conductor terminals (neutral bar) complies with the conditions of the last sentence of Section 408.40 of the *National Electrical Code*®.

6.9 PROPER TYPE OR CLASS AND RATING

When installing circuit breakers or fuses, ensure that they are of the proper type or class and rating.

6.10 DEBRIS

Clean the cabinet of all debris, which has accumulated during the panelboard installation Ensure that all foreign materials, including cement, plaster and paint (overspray) are cleaned and removed. Remove all such materials with great care to avoid damage to conductors, plating, etc. (see 6.4.1).

6.11 STEPS IN SECTION 7

If the job is complete, perform the steps in Section 7 and then install the cabinet front (see Section 8).

© 2014 National Electrical Manufacturers Association

Section 7
STEPS TO BE TAKEN BEFORE ENERGIZING

7.1 ACCESSIBLE ELECTRICAL CONNECTIONS

Tighten all accessible electrical connections to the manufacturer's torque specifications. If such information is not provided with the equipment, consult the manufacturer.

7.2 BLOCKS AND PACKING MATERIALS

Make certain that all blocks and packing materials used for shipment have been removed from all component devices and the panelboard.

7.3 SWITCHES, CIRCUIT BREAKERS, AND OTHER OPERATING MECHANISMS

Manually exercise all switches, circuit breakers, and other operating mechanisms to make certain they operate freely. If devices with self-test function are installed, perform test and verify proper operation per the manufacturer's instructions.

Check the integrity of all electrical and mechanical interlocks and padlocking mechanisms. For key interlocked systems, assure that only the required number of keys are accessible to the operator.

7.4 SHORT CIRCUITS AND GROUND FAULTS

To make sure that the system is free from short circuits and ground faults, conduct an insulation resistance test phase to ground and phase to phase with the switches or circuit breakers in both the open and closed positions. If the resistance reads less than 1 megohm while testing with the branch circuit devices in the open position, the system may be unsafe and should be investigated. If after investigation and possible correction, low readings are still observed, the manufacturer should be contacted. Some electronic equipment (metering, SPD, etc.) may be damaged by this testing. Refer to the manufacturers equipment markings for guidelines.

7.5 GROUND FAULT PROTECTION SYSTEM

Test the ground fault protection system (if furnished) in accordance with the manufacturer's instructions. See Section 230.95 of the *National Electrical Code*® and NEMA PB 2.2, *Application Guide for Ground Fault Protective Devices for Equipment*.

7.6 ADJUSTABLE TIME CURRENT TRIP DEVICE SETTINGS

Set any adjustable time current trip device settings to the proper values.

NOTE—Experience has indicated that damage from overcurrent can be reduced if the devices used for overload and short-circuit protection are set to operate instantaneously (that is, without intentional time delay) at 115 percent of the highest value of phase current which is likely to occur as the result of any anticipated motor starting or welding currents.

7.7 GROUNDING CONNECTIONS

Check to determine that all grounding connections are properly made. If the panelboard is used as service equipment, make certain that the neutral, if present, is properly bonded to the cabinet.

© 2014 National Electrical Manufacturers Association

7.8 FOREIGN MATERIAL

Remove all foreign material from the panelboard and cabinet before installing the cabinet front. Make certain that all deadfront shields are properly aligned and tightened. Install the cabinet front in accordance with Section 8.

© 2014 National Electrical Manufacturers Association

Section 8
INSTALLATION OF CABINET FRONT

8.1 CABINET FRONT OR TRIM PACKAGE

The cabinet front or trim package is designed to prevent damage to the front during shipment and handling.

8.2 UNPACKING

Care should be used when unpacking and handling the cabinet front.

8.3 COVERS AND DOORS

Install covers, close doors, and make certain that no conductors are pinched and that all enclosure parts are properly aligned and tightened. Hinged covers or doors must open a minimum of 90 degrees when installed.

8.4 TOUCH-UP

A suitable paint or other corrosion-resistant finish should be applied to those places where the finish is damaged.

8.5 FRONT ALIGNMENT

The cabinet front may be provided with an adjusting means to align it squarely with the building even though the cabinet may be slightly out of plumb with the building.

© 2014 National Electrical Manufacturers Association

Section 9
ENERGIZING EQUIPMENT

WARNING—HAZARDOUS VOLTAGES IN ELECTRICAL EQUIPMENT CAN CAUSE SEVERE PERSONAL INJURY OR DEATH. ENERGIZING A PANELBOARD FOR THE FIRST TIME AFTER INITIAL INSTALLATION OR MAINTENANCE IS POTENTIALLY DANGEROUS.

9.1 QUALIFIED PERSONNEL

Only qualified personnel should energize equipment for the first time. If short circuit conditions caused by damage or poor installation practices have not been detected in the procedures specified in Section 7, serious personal injury and damage can occur when the power is turned on.

9.2 LOAD ON THE PANELBOARD

There should be no load on the panelboard when it is energized. Turn off all of the downstream loads.

9.3 ENERGIZED IN SEQUENCE

The equipment should be energized in sequence by starting at the source end of the system and working towards the load end. In other words, energize the main devices, then the feeder devices, and then the branch-circuit devices. Turn the devices on with a firm positive motion.

9.4 LOADS SUCH AS LIGHTING CIRCUITS, CONTACTORS, HEATERS, AND MOTORS

After all main, feeder, and branch circuit devices have been closed, loads such as lighting circuits, contactors, heaters, and motors may be turned on.

© 2014 National Electrical Manufacturers Association

Section 10
MAINTENANCE

10.1 MAINTENANCE PROGRAM

A maintenance program for panelboards should be conducted on a regularly scheduled basis in accordance with the following:

10.2 PANELBOARD WHICH HAS BEEN CARRYING ITS REGULAR LOAD FOR AT LEAST 3 HOURS

A panelboard which has been carrying its regular load for at least 3 hours just prior to inspection should be field tested by feeling the deadfront surfaces of circuit breakers, switches, interior trims, doors, and enclosure sides with the palm of the hand. If the temperature of these surfaces does not permit you to maintain contact for at least 3 seconds, this may be an indication of trouble and investigation is necessary. Thermographic (infrared) scanning has become a useful method of investigating thermal performance.

WARNING—HAZARDOUS VOLTAGES IN ELECTRICAL EQUIPMENT CAN CAUSE SEVERE PERSONAL INJURY OR DEATH. UNLESS OTHERWISE SPECIFIED, INSPECTION AND MAINTENANCE SHOULD ONLY BE PERFORMED ON PANELBOARDS TO WHICH POWER HAS BEEN TURNED OFF, DISCONNECTED AND ELECTRICALLY ISOLATED SO THAT NO ACCIDENTAL CONTACT CAN BE MADE WITH ENERGIZED PARTS. FOLLOW ALL MANUFACTURER'S WARNINGS AND INSTRUCTIONS.

Safety related work practices, as described in NFPA 70E, should be followed at all times.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE PANELBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE PANELBOARD COMPONENTS DURING INSTALLATION OR MAINTENANCE.

10.3 INSPECT PANELBOARD ONCE EACH YEAR

Inspect the panelboard once each year or after any severe short circuit.

10.4 ACCUMULATION OF DUST AND DIRT

If there is an accumulation of dust and dirt, clean out the panelboard by using a brush, vacuum cleaner, or clean lint-free rags. Avoid blowing dust into circuit breakers or other components. Do not use a blower or compressed air.

10.4.1 Visible Electrical Joints and Terminals

Carefully inspect all visible electrical joints and terminals in the bus and wiring system.

10.4.2 Conductors and Connections

Visually check all conductors and connections to be certain that they are clean and secure. Loose and/or contaminated connections increase electrical resistance which can cause overheating. Such overheating is indicated by discoloration or flaking of insulation and/or metal parts. Pitting or melting of connecting surfaces is a sign of arcing due to a loose or otherwise poor connection. Parts which show evidence of overheating or looseness should be cleaned and re-torqued or replaced if damaged. Tighten bolts and nuts at bus joints to manufacturer's torque specifications.

© 2014 National Electrical Manufacturers Association

CAUTION—DO NOT REMOVE PLATING FROM ALUMINUM PARTS IN JOINTS OR TERMINATIONS. DAMAGE TO PLATING CAN RESULT IN OVERHEATING. REPLACE DAMAGED ALUMINUM PARTS.

10.4.3 Fuse Clip Contact Pressure and Contact Means

Examine fuse clip contact pressure and contact means. If there is any sign of overheating or looseness, follow the manufacturer's maintenance instructions or replace the fuse clips. Loose fuse clips can result in overheating.

10.4.4 Plug Fuses

Re-tighten plug fuses.

10.4.5 Conditions Which Caused Overheating

Be sure that all conditions which caused the overheating have been corrected.

10.5 PROPER AMPERE, VOLTAGE, AND INTERRUPTING RATINGS

Check circuit breakers, switches, and fuses to ensure they have the proper ampere, voltage, and interrupting ratings. Ensure that non-current-limiting devices are not used as replacements for current-limiting devices. Never attempt to defeat rejection mechanisms which are provided to prevent the installation of the incorrect class of fuse.

10.5.1 Mechanisms Free and in Proper Working Order

Operate each switch or circuit breaker several times to ensure that all mechanisms are free and in proper working order. Replace as required. See NEMA AB-4 for maintenance of molded case circuit breakers.

10.6 OPERATION OF ALL MECHANICAL COMPONENTS

Check the operation of all mechanical components. Replace as required.

10.6.1 Switch Operating Mechanisms

Exercise switch operating mechanisms and external operators for circuit breakers to determine that they operate freely to their full on and off positions.

10.6.2 Integrity of Electrical and Mechanical Interlocks

Check the integrity of all electrical and mechanical interlocks and padlocking mechanisms. For key interlocked systems, assure that only the required number of keys are accessible to the operator.

10.6.3 Missing or Broken Parts

Whenever practical, check all devices for missing or broken parts, proper spring tension, free movement, corrosion, dirt, and excessive wear.

10.6.4 Manufacturer's Instructions

Adjust, clean, and lubricate or replace parts according to the manufacturer's instructions.

10.6.4.1 Clean Nonmetallic Light Grease or Oil

Use *clean* nonmetallic light grease or oil as instructed.

10.6.4.2 Molded Case Circuit Breakers

Do *not* oil or grease parts of molded case circuit breakers.

© 2014 National Electrical Manufacturers Association

10.6.4.3 Clean, Light Grease

If no instructions are given on the devices, sliding copper contacts, operating mechanisms, and interlocks may be lubricated with clean, light grease.

10.6.4.4 Excess Lubrication

Wipe off excess lubrication to avoid contamination.

CAUTION—HYDROCARBON SPRAY PROPELLANTS AND HYDROCARBON BASED SPRAYS OR COMPOUNDS WILL CAUSE DEGRADATION OF CERTAIN PLASTICS. CONTACT THE PANELBOARD MANUFACTURER BEFORE USING THESE PRODUCTS TO CLEAN, DRY, OR LUBRICATE PANELBOARD COMPONENTS DURING INSTALLATION OR MAINTENANCE.

10.6.5 Accessible Copper Electrical Contacts, Blades, and Jaws

Clean and dress readily accessible copper electrical contacts, blades, and jaws according to the manufacturer's instructions when inspection indicates the need.

10.7 DAMAGED INSULATING MATERIAL AND ASSEMBLIES

Look for and replace damaged insulating material and assemblies where sealing compounds have deteriorated.

10.8 MOISTURE OR SIGNS OF PREVIOUS WETNESS OR DRIPPING

Look for any moisture or signs of previous wetness or dripping inside the cabinet.

NOTE—Condensation in conduits or dripping from outside sources is one known cause of panelboard malfunction.

10.8.1 Conduits Which Have Dripped Condensate

Seal off any conduits which have dripped condensate, and provide means for further condensate to drain away from the panelboard.

10.8.2 Cracks or Openings

Seal off any cracks or openings which have allowed moisture to enter the enclosure. Eliminate the source of any dripping on the enclosure and any other source of moisture.

10.8.3 Insulating Material Which is Damp or Wet

Replace or thoroughly dry and clean any insulating material, which is damp or wet or shows an accumulation of deposited material from previous wettings.

10.8.4 Component Devices Which Show Evidence of Moisture Damage

Inspect all component devices. Replace any component device which shows evidence of moisture damage or has been subjected to water damage or flooding. Additional information may be found in the NEMA document “Guidelines for Handling Water Damaged Electrical Products.”

10.9 BEFORE CLEANUP AND CORRECTIVE ACTION IS ATTEMPTED

In the event of water damage, e.g., flooding or sprinkler discharge, the manufacturer should be consulted before clean up and corrective action is attempted.

© 2014 National Electrical Manufacturers Association

10.10 SEVERE ELECTRICAL SHORT CIRCUIT

If a severe electrical short circuit has occurred, the excessive currents may have resulted in structural component and/or bus and conductor damage due to mechanical distortion, thermal damage, metal deposits, or smoke. Examine all devices and bus supports for cracks or breakage. The manufacturer should be consulted before cleanup and correction is attempted.

10.11 GROUND FAULT PROTECTION SYSTEM

Test the ground fault protection system (if furnished) in accordance with the manufacturer's instructions. See Section 230.95 of the *National Electrical Code*® and NEMA PB 2.2 *Application Guide for Ground Fault Protective Devices for Equipment.*

10.12 INSULATION RESISTANCE

Check insulation resistance (see 7.4) under any of the following conditions:

10.12.1 Severe Short Circuit

If a severe short circuit has occurred (see 10.10);

10.12.2 Parts Replaced

If it has been necessary to replace parts or clean insulating surfaces;

10.12.3 Panelboard Exposed to High Humidity

If the panelboard has been exposed to high humidity, condensation, or dripping moisture.

© 2014 National Electrical Manufacturers Association

Section 11
PERMISSIBLE LOADING OF PANELBOARDS

11.1 *NATIONAL ELECTRICAL CODE®*

In compliance with the *National Electrical Code*®, the normal continuous loads (3 hours or more) of panelboard circuits should be not more than 80 percent of the rating of the overcurrent protective device, unless the marking of the device indicates that it is suitable for continuous duty at 100 percent of its rating.

11.2 HARMONICS IN ELECTRICAL SYSTEM

Some types of electrical equipment cause harmonics in the electrical system, which may result in overheating. This condition should be considered when determining panelboard loading.

Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

Introduction

This bulletin provides instructions for installing I-Line™ Plug-on Units with Surgelogic™ Surge Protective Devices (SPDs) into I-Line panelboards and switchboards.

This is a supplement to the information manual provided with each panelboard and the instruction bulletin provided with each switchboard.

Note: For troubleshooting, call the Surgelogic Technical Assistance Group at 1-800-577-7353.

Proper installation is imperative to maximize the surge protective device's effectiveness and performance. To ensure proper installation, follow the steps outlined in this instruction bulletin. Read the entire instruction bulletin before beginning the installation. These instructions are not intended to replace national or local electrical codes. Check all applicable electrical codes to verify compliance. Installation of modular surge suppressors should only be performed by qualified electrical personnel.

Unpacking and Preliminary Inspection

Inspect the entire shipping container for damage or signs of mishandling before unpacking the device. Remove the packing material and further inspect the device for any obvious shipping damage. If any damage is found and is a result of shipping or handling, immediately file a claim with the shipping company.

Storage

The device should be stored in a clean, dry environment. Storage temperature is -40 °F to +149 °F (-40 °C to +65 °C). All of the packaging materials should be left intact until the device is ready for installation.

Safety Labels

English, Spanish, and French versions of all safety labels (Danger, Warning, and Notice) are provided.

Identification Nameplate

The identification nameplate is located on the front surface next to the diagnostic display.

Figure 1: Surge Protective Device Nameplate Example

⚠ CAUTION

LOSS OF BRANCH CIRCUIT POWER/LOSS OF SURGE SUPPRESSION

- Perform periodic inspection of the Surge Protective Device status indicator lights as part of the preventative maintenance schedule.
- Promptly service the Surge Protective Device when an alarm state exists.
- Use dry contacts to signal an alarm state to the central supervisory system for unmanned, inaccessible, or critical installations.
- Use multiple Surge Protective Devices to achieve redundancy for critical applications.

Failure to follow these instructions can result in injury or equipment damage.

At end-of-life conditions, Surge Protective Devices (SPDs) can lose their ability to block power system voltage and attempt to draw excessive current from the line. This SPD is equipped with overcurrent and overtemperature components that will automatically disconnect the surge suppression elements from the mains should the surge suppression elements reach end of life. Also, at that time, tripping of the branch circuit breaker or fuse feeding the SPD can occur.

© 2010–2016 Schneider Electric USA All Rights Reserved

⚠ CAUTION

LOSS OF SURGE SUPPRESSION

- Do not energize the Surge Protective Devices until the electrical system is completely installed, inspected, tested, and all conductors have been connected and functional, including the neutral.
- Verify the voltage rating of the device and system before energizing the Surge Protective Device.
- Disconnect the Surge Protective Device, including the neutral, from the power source before performing high-potential insulation testing or any tests where Surge Protective Device components will be subjected to voltages higher than their rated turn-on voltage.

Failure to follow these instructions can result in injury or equipment damage.

Location Considerations

Environment

The device is designed to operate in an ambient temperature range of -4 °F to +149 °F (-20 °C to +65 °C) with a relative humidity of 0 to 95% non-condensing. The operating temperature of the LCD on the diagnostic display panel is +14 °F to +140 °F (-10 °C to +60 °C). Refer to the product catalog for further details on enclosures. All I-Line devices operate normally without reduction in performance when subjected to shock and vibrations described in IEC 60721-3-3, Class 3M4.

Audible Noise

The device background noise is negligible and does not restrict the location of the installation.

Service Clearance

The service clearance should meet all applicable code requirements.

Electrical

Voltage Rating

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Confirm the Surge Protective Device voltage rating on the module or nameplate label is the same as the operating voltage.

Failure to follow these instructions will result in death or serious injury.

Prior to mounting the SPD, verify that the device has the same voltage rating as the power distribution system in which it is installed. Compare the nameplate voltage or model number on the SPD with the nameplate of the electrical distribution equipment.

ENGLISH

The specifier or user of the device must be familiar with the configuration and arrangement of the power distribution system in which any SPD is to be installed. The system configuration of any power distribution system is based strictly on how the secondary windings of the transformer supplying the service entrance main or load are configured. This includes whether or not the transformer windings are referenced to earth via a grounding conductor. The system configuration is not based on how any specific load or equipment is connected to a particular power distribution system.
See Table 1 for the service voltage of each SPD.

General

The I-Line device has SPD elements connected from phase to ground. To prevent hazardous touch voltage on the I-Line enclosure during normal operation or during SPD end-of-life, it is critical that there be a robust and effective connection to the building grounding structure. The grounding connection must utilize an equipment grounding conductor run with the phase and neutral (if present) connection of the power system. Do not connect the I-Line device to a separate isolated ground.

For best overvoltage suppression by the I-Line device, use a single-point ground system where the service entrance grounding electrode system is connected to and bonded to all other available electrodes, building steel, metal water pipes, driven rods, etc. (for reference, see NEC Art 250). The ground impedance measurement should be in compliance with all applicable codes.

Solidly-Grounded Power Systems

⚠ CAUTION

SURGE PROTECTIVE DEVICE DAMAGE AND POWER SYSTEM OVERVOLTAGE

- Do not connect devices rated for use on solidly-grounded power systems to resistance-grounded (for example, High Resistance Ground) or ungrounded power systems.
- Verify that the service entrance equipment is bonded to ground in accordance with all applicable codes.
- Verify that the neutral terminal of the power system transformer feeding the device is bonded to system ground in accordance with all applicable codes.

Failure to follow these instructions can result in equipment damage.

SPDs rated for use on solidly-grounded power systems must not be connected to resistance-grounded or ungrounded power systems. Such a connection can result in damage to the SPD.

Always verify the power system grounding configuration prior to application of power to the device. Confirm that all ground bonds are installed at both the service entrance equipment and power system transformer prior to application of power.

Delta and Resistance-Grounded Power Systems

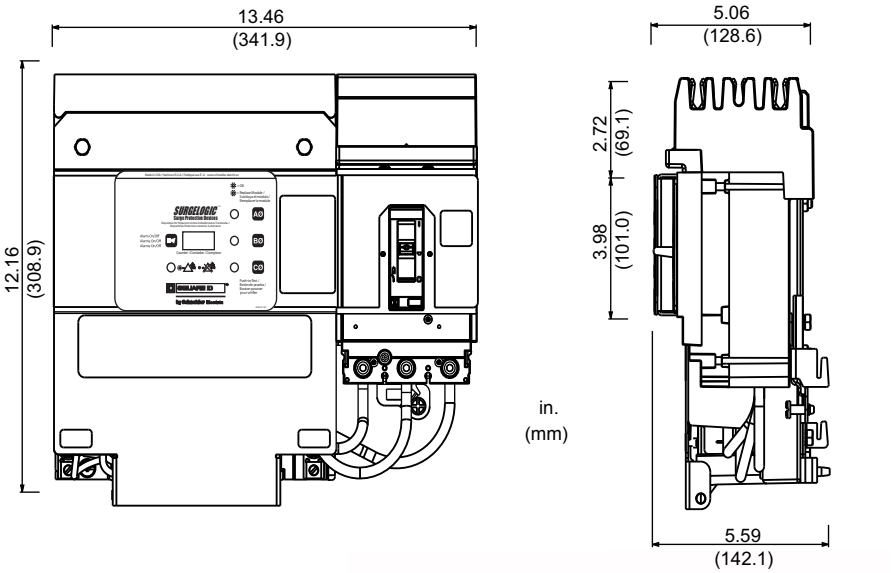
⚠ CAUTION

SURGE PROTECTIVE DEVICE DAMAGE AND POWER SYSTEM OVERVOLTAGE

- Ungrounded power systems are inherently unstable and can produce excessively high line-to-ground voltages during certain fault conditions. During these fault conditions any electrical equipment, including an SPD, may be subjected to voltages which exceed their designed ratings. This information is being provided to the user so that an informed decision can be made before installing any electrical equipment on an ungrounded power system.
- Resistance-grounded power systems must be maintained in an over-damped state to limit voltage overshoot and duration during operation.
- Perform verification and adjustment of correct power system damping:
  - — Periodically as part of normal system maintenance.
  - — Following power system modifications.

Failure to follow these instructions can result in equipment damage.

The I-Line product is intended for use on resistance-grounded power systems where the power system has been set for, and is maintained in, an over-damped state. For the power system to be over-damped, the current through the grounding resistor during a bolted phase-to-ground fault must be significantly greater than the total charging current of the system.



Periodic engineering evaluation of the power system is required to determine the worst-case charging current of the system and to adjust the grounding resistance accordingly. As the power system is modified, the value of the grounding resistor must be evaluated and adjusted to maintain the system in the over-damped state.

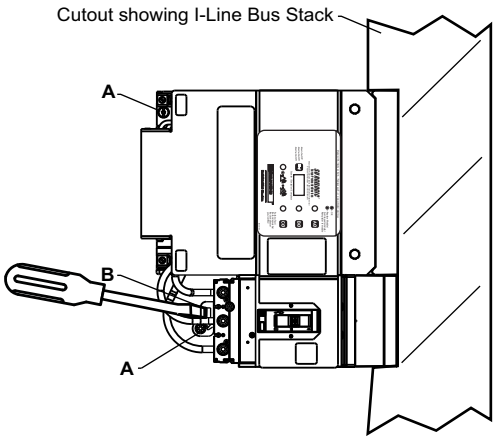
HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH



- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

⚠CAUTION

LOSS OF SURGE SUPPRESSION

- Verify that the service entrance equipment is bonded to ground in accordance with all applicable codes.
- Verify that the neutral bonding jumper is installed at the service entrance in accordance with all applicable codes.
- When neutral is not present at the I-Line panel, connect Surge Protective Device neutral and ground together with a minimum 10 AWG wire.

Failure to follow these instructions can result in equipment damage.

Figure 5: Blank Extensions in Deadfront

Turn off all power supplying the panelboard or switchboard before working on or installing the I-Line Surgelogic device.

1. Turn off all power supplying the panelboard or switchboard before working on or installing the I-Line Surgelogic device.
2. Loosen the retaining screws (**A**) (see Figure 4).
3. Place the device on the I-Line pan with the jaws pushed against the bus.
4. Insert a flat-head screwdriver into the screwdriver slot (**B**). Rack the device onto the bus.
5. Tighten the two retaining screws (**A**).
6. Use 6 AWG copper wire to connect the ground and neutral assembly from the SPD to the panelboard or switchboard neutral and ground.

   Note: The wires should be as short as possible. Torque each neutral and ground connection to 35 lb-in. (4 N•m).
7. Close all openings around the Surgelogic device.
8. Ensure blank extensions (**C**) are installed into the deadfront whenever the I-Line Surgelogic device is placed on the wide side of the bus stack (see Figure 5).

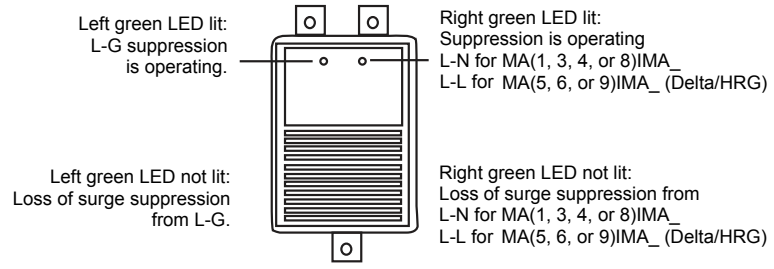
LED Status Indicators

Figure 7: Three-Phase Diagnostic Display Panel with Surge Counter (TVS3DSPHIC; TVS1DSPHIC for TVS1 series devices)



Note: Phase B is not present on single-phase application.

The SPD diagnostic display panel shows the status of each MA module with diagnostically controlled green/red LEDs (**A**). If a unit is operating correctly, all the phase LEDs will be illuminated green. To test the integrity of the diagnostics for each phase, push the corresponding phase button **(B)** on the diagnostic display panel. If the alarm is enabled, the green LEDs will turn red, the dry contacts will change state, and the alarm will sound. Releasing the test button (**B**) will complete the test; the LEDs will turn green, the dry contacts will change back to a normal state, and the alarm will shut off (see Figure 7).

If an inoperable condition occurs on any phase, the audible alarm sounds (if enabled), the dry contacts will switch to an error state and the corresponding phase LED (**A**) on the diagnostic display panel is illuminated red. This indicates that the device needs service by qualified electrical personnel. The audible alarm can be silenced by pressing the alarm enable/disable button (**C**). The alarm will silence and the green alarm LED (**D**) will not be illuminated. The red phase LED will continue to be illuminated until the inoperative condition has been cleared (see Figure 7).

Figure 8: MA Module LEDs

© 2010–2016 Schneider Electric USA All Rights Reserved

On an MA module (see Figure 8), when the power is applied, if the left green LED is not lit, it indicates a loss of suppression from line-to-ground for that phase. If the right green LED is not lit, it indicates a loss of suppression from line-to-neutral for that phase. If either LED is not lit the module should be replaced.

When power is applied to the SPD and one or more of the diagnostic display panel LEDs are red, and one or more MA module LEDs are out, the appropriate MA module should be replaced. (see Table 2).

Refer to “Maintenance and Troubleshooting” on page 16 for proper troubleshooting procedures. If the module LEDs are green and the diagnostic display LEDs are red, please call SPD TAG at 1-800-577-7353.

Power System Grounding

In addition to the power system configuration and voltage, the power system grounding method must be considered when selecting the appropriate I-Line device. Refer to the following chart for information concerning the suitability of I-Line device to specific power system grounding method.

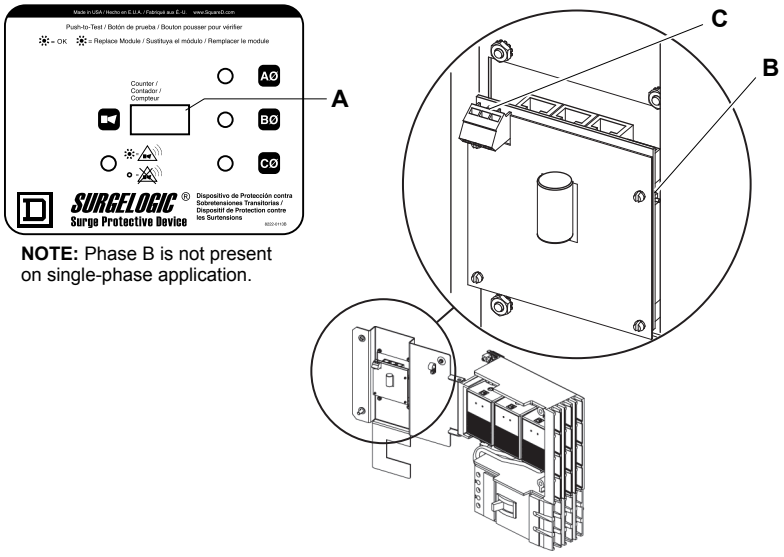
Audible Alarm

Figure 9: Alarm Enable/Disable

Note: Phase B is not present on single-phase application.

Push the alarm enable/disable button (**A**, Figure 9), to enable or disable the alarm.

- If the green LED (**B**) is illuminated the alarm is enabled.
- If the green LED (**B**) is not illuminated the alarm is disabled.



Surge Counter

Note: Refer to “Access to MA Modules and Back of Diagnostic Display Panel” on page 11, for instructions on accessing the rear of the diagnostic display panel to reset the surge counter.

The surge counter (**A**, Figure 10), displays the number of transient voltage surges since the counter was last reset. The counter is battery powered to retain memory in the event of a power loss to the diagnostic display panel.

To reset the counter to zero, press the counter reset button (**B**) located inside the unit on the underside of the diagnostic circuit board.

Figure 10: Three-Phase Diagnostic Display Panel with Surge Counter

NOTE: Phase B is not present on single-phase application.

Dry Contacts

The I-Line series Surge Protective Device (SPD) is provided with dry contacts. The connection for the dry contacts (**C**, Figure 10), is located and labeled on the back of the diagnostic display panel and will accept 22-14 AWG stranded or solid wire. The dry contacts are three-position, Form “C” type with Normally Open, Normally Closed and Common connections. The unpowered state shall be closed between terminals NC and COM. This is also the alarm condition. The opposite state, closed between terminals NO and COM, indicates that power is on to the unit and that no alarm condition exists (see Table 3).

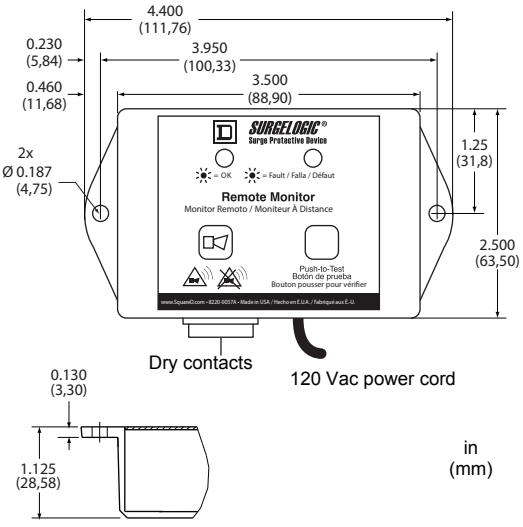
Table 3: Dry Contact Configuration

Alarm Contact Terminals	Contact State with Power Applied
NO to COM	Closed
NC to COM	Open



These contacts can be used for remote indication of the SPD's operating status to a computer interface board or emergency management system. Also, these contacts are designed to work with the SPD remote monitor option described below.

Care must be taken when installing the dry contact wiring because the terminals are on a moving door. Avoid the door hinge, any switches, and the high voltage areas of the enclosure when routing the wiring. To avoid the door hinge, tie wrap any dry contact wiring to the existing cable harness which crosses the hinge. Once the dry contact wiring is secured on a non-moving point of the enclosure, it is the user's responsibility to maintain at least 1.0 in. (25 mm) separation between 600 Vac rated dry contact wiring and the power wiring in the enclosure.

The contacts are designed for a maximum voltage of 24 Vdc / 24 Vac and a maximum current of 2 A. Higher energy applications may require additional relay implementation outside the SPD. Damage to the SPD's relay caused by use with energy levels in excess of those discussed in this instruction bulletin are not covered by warranty. For application questions, contact the Surgelogic Technical Assistance Group at 1-800-577-7353.

Remote Monitor Option

Figure 11: Remote Monitor Option (TVS12RMU)

The remote monitor option has two LEDs, one red and one green, and an audible alarm with an enable/disable switch. Normal status is an illuminated green LED, and no audible alarm. To test the integrity of the remote monitor, press the pushto-test switch. If the alarm is enabled, the green LED will turn off, the red LED will turn on, and the alarm will sound. Releasing the switch will complete the test; the red LED will turn off, the green LED will turn on and the alarm will shut off.

If suppression on any phase is lost, the green LED will turn off, the red LED will turn on and an alarm will sound. The audible alarm can be silenced by pushing the alarm enable/disable button. The alarm will silence and the green alarm LED will not be illuminated. The red LED will continue to be illuminated until the inoperative condition has been cleared.

The remote monitor includes a 120 Vac to 12 Vdc adapter with a six-foot power cord. Connections are made to the SPD diagnostic panel with Form "C", three-position dry contacts (provided), and the appropriate length of solid or stranded 22–14 AWG wire up to 1000 ft. (305 m), not provided.

Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

⚠ CAUTION

LOSS OF BRANCH CIRCUIT POWER/LOSS OF SURGE SUPPRESSION

- Ensure that the branch circuit breaker or fuse trip characteristic has been coordinated with the overcurrent components inside the SPD (See Tables 1 and 2).
- Perform periodic inspection of the SPD status indicator lights as part of the preventative maintenance schedule.
- Promptly service the SPD when an alarm state exists.
- Use dry contacts to signal an alarm state to the central supervisory system for unmanned, inaccessible, or critical installations.
- Use multiple SPDs to achieve redundancy for critical applications.

Failure to follow these instructions can result in injury or equipment damage.

Surge Protective Devices (SPDs) can lose their ability to block power system voltage and attempt to draw excessive current from the line.This SPD is equipped with overcurrent and overtemperature components that will automatically disconnect the surge suppression elements from the mains should the surge suppression elements reach end of life. Tripping of the branch circuit breaker or fuse feeding the SPD can occur when the surge suppression elements reach end of life. Mitigate the tripping of the branch circuit breaker or fuse feeding the SPD by coordinating the surge suppression elements with the branch circuits.

For the purposes of coordination, the SPD is equipped with overcurrent components that will limit the per phase I2t, Iapparent, Ip, and Ith values to those listed in tables 1 and 2 when connected to a power system with a short-circuit current rating not exceeding 200,000 A.

⚠ CAUTION

LOSS OF SURGE SUPPRESSION

- Do not energize the SPDs until the electrical system is completely installed, inspected, tested, and all conductors connected and functional, including the neutral.
- Verify the voltage rating of the device and system before energizing the surge protective device.
- Perform high-potential insulation testing, or any other tests where SPD components will be subjected to voltages higher than their rated turn-on voltage, with the neutral and SPD disconnected from the power source.

Failure to follow these instructions can result in injury or equipment damage.

LED Status Indicators

The SPD diagnostic display panel shows the status of each MA module with diagnostically controlled green/red LEDs. If a unit is operating correctly, all the phase LEDs will be illuminated green. To test the integrity of the diagnostics for each phase, push the button below the phase LEDs on the diagnostic display panel. The green LED will turn red and the alarm will sound, if the alarm is enabled. Releasing the test button will complete the test; the red LED will turn green and the alarm will shut off.

If an inoperable condition occurs on any phase, the audible alarm sounds and the corresponding phase LED on the diagnostic display panel is illuminated red. This indicates that the device needs service by qualified electrical personnel. The audible alarm can be silenced, until a qualified person is able to evaluate and service the SPD, by pressing the alarm enable/disable button. The alarm will silence and the green alarm LED will not be lit. The red phase LED will continue to be illuminated until the inoperative condition has been cleared.

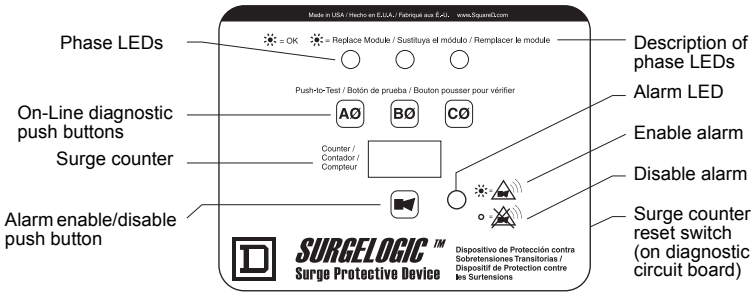
Figure 1: MA Module LEDs

On an MA module (see Figure 1), if either LED is not lit, the module should be replaced. If both green LEDs are not lit and the diagnostic display panel has power, then power has been lost to that phase or the module should be replaced (refer to Table 4 on page 7). Refer to the final equipment instruction bulletin for MA module disconnection and access instructions.

When power is applied to the SPD and one or more of the diagnostic display panel LEDs are red, and one or more MA module LEDs are out, the appropriate MA module should be replaced. Refer to “Troubleshooting” on page 8 for proper troubleshooting procedures.

Surge Counter

The surge counter displays the number of transient voltage surges since the counter was last reset. The counter is battery powered to retain memory in the event of a power loss to the diagnostic display panel.



To reset the surge counter to zero:

1. Remove all power from this equipment.
2. Remove covers as necessary to gain access to the diagnostic circuit board.
3. Press the small switch located on the underside of the diagnostic circuit board (near the RJ45 connectors; see Figure 3:). This will reset the counter to zero.

Dry Contacts

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Use 600 Vac rated dry contact wiring.
- Dry contact wiring must have less than 1/16 in. (1.6 mm) exposed wire from the dry contact block.
- Maintain at least 1.0 in. (25 mm) separation between dry contact wiring and the power wiring in the enclosure.

Failure to follow these instructions will result in death or serious injury.

The IMA series SPD is provided with dry contacts. The connection for the dry contacts is located on the back of the diagnostic display panel (lower right corner). The dry contacts are 3-position, Form “C” type with Normally Open, Normally Closed and Common connections. The unpowered state shall be closed between terminals NC and COM. This is also the alarm condition. The opposite state, closed between terminals NO and COM, indicates that power is on to the unit and that no alarm condition exists (See Table 3).

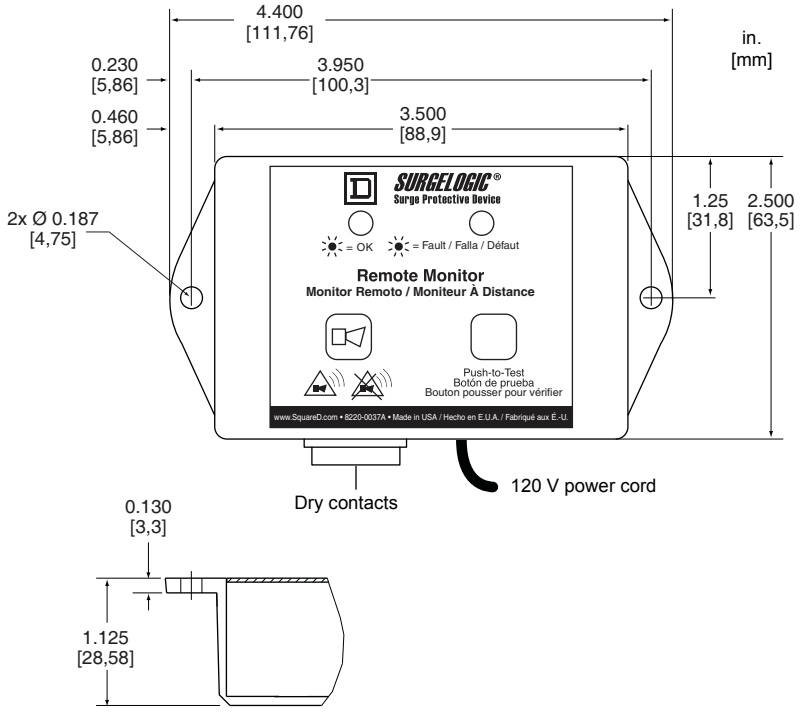
Table 3: Dry Contact Configuration

Alarm Contact Terminals	Contact State with Power Removed
NC	Normally closed
COM	Common
NO	Normally open

These contacts can be used for remote indication of the SPD device's operating status to a computer interface board or emergency management system. Also, these contacts are designed to work with the SPD remote monitor option described below.

The contacts are designed for a maximum voltage of 24 Vdc / 24 Vac and a maximum current of 2 A. Higher energy applications may require additional relay implementation outside the SPD. Damage to the SPD's relay caused by use with energy levels in excess of those discussed in this instruction bulletin are not covered by warranty. For application questions, contact the Surgelogic Technical Assistance Group at 1-800-577-7353.



Remote Monitor Option

The option has two LEDs, one red and one green, and an audible alarm with an enable/disable switch. Normal status is a lit green LED, and no audible alarm. To test the integrity of the remote monitor, press the push-to-test switch.

The green LED will turn off, the red LED will turn on, and the alarm will sound, if the alarm is enabled. Releasing the switch will complete the test; the red LED will turn off, the green LED will turn on and the alarm will shut off. If suppression on any phase is lost, the green LED will turn off, the red LED will turn on and an alarm sounds. The audible alarm can be silenced by moving the alarm enable/disable switch to the disable position. The alarm will silence and the green alarm LED will not be lit. The red LED will continue to be illuminated until the inoperative condition had been cleared.

The remote monitor includes a 120 Vac to 12 Vdc adapter with a six-foot power cord. Connections are made to the SPD diagnostic display panel with Form "C", 3-position dry contacts (provided) and the appropriate length of solid or stranded 30 to 14 AWG wire (not provided).

Maintenance and Troubleshooting

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

Preventive Maintenance

Inspect the SPD periodically to maintain reliable system performance and continued transient voltage surge suppression. Periodically check the state of the diagnostic display panel LED status indicators. Routinely use the built-in diagnostics to inspect for inoperative modules.

Precautions

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

⚠ CAUTION

LOSS OF BRANCH CIRCUIT POWER/LOSS OF SURGE SUPPRESSION

- Ensure that the branch circuit breaker or fuse trip characteristic has been coordinated with the overcurrent components inside the Surge Protective Device (See Tables 1 and 2).
- Perform periodic inspection of the Surge Protective Device status indicator lights as part of the preventative maintenance schedule.
- Promptly service the Surge Protective Device when an alarm state exists.
- Use dry contacts to signal an alarm state to the central supervisory system for unmanned, inaccessible, or critical installations.
- Use multiple Surge Protective Devices to achieve redundancy for critical applications.

Failure to follow these instructions can result in injury or equipment damage.

At end-of-life conditions, Surge Protective Devices (SPDs) can lose their ability to block power system voltage and attempt to draw excessive current from the line. This SPD is equipped with overcurrent and overtemperature components that disconnect the surge suppression elements from the electrical supply should the surge suppression elements reach end of life. Tripping of the branch circuit breaker or fuse feeding the SPD can occur when the surge suppression elements reach end of life.

The SPD is equipped with overcurrent components that will limit the per phase I^2t, $I_{apparent}$, I_p, and I_{th} values to those listed in Tables 1 and 2 when connected to a power system with a short-circuit current rating not exceeding 200,000 A.

1 Catalog numbers are representational. Model numbers are not recognized in the Schneider Electric™ ordering system until a suffix code is applied.

⚠ CAUTION

LOSS OF SURGE SUPPRESSION

- Do not energize the Surge Protective Devices until the electrical system is completely installed, inspected, tested, and all conductors have been connected and functional, including the neutral.
- Verify the voltage rating of the device and system before energizing the Surge Protective Device.
- Perform high-potential insulation testing, or any other tests where Surge Protective Device components will be subjected to voltages higher than their rated turn-on voltage, with the neutral and Surge Protective Device disconnected from the power source.

Failure to follow these instructions can result in injury or equipment damage.

Introduction

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

NOTE: For troubleshooting, call the Surgelogic Technical Assistance Group at 1-800-577-7353.

Proper installation is imperative to maximize the NQ SurgeLoc Assembly SPD's effectiveness and performance. The installer should follow the steps outlined in this instruction bulletin to ensure proper installation. Read the entire instruction bulletin before beginning the installation. These instructions are not intended to replace national or local electrical codes. Check all applicable electrical codes to verify compliance. Installation of NQ brick surge suppressors should only be performed by qualified electrical personnel.

Unpacking and Preliminary Inspection

Inspect the entire shipping container for damage or signs of mishandling before unpacking the device. Remove the packing material and further inspect the device for any obvious shipping damage. If any damage is found and is a result of shipping or handling, immediately file a claim with the shipping company.

Storage

The device should be stored in a clean, dry environment. Storage temperature is -40 °F to +149 °F (-40 °C to +65 °C). All of the packaging materials should be left intact until the device is ready for installation.

Safety Labels

English, Spanish, and French versions of all safety labels (Danger, Warning, and Notice) are provided.

Surge Protective Device (SPD) Location Considerations

Environment

The device is designed to operate in an ambient temperature range of -4 °F to +104 °F (-20 °C to +40 °C) with a relative humidity of 0 to 95% non-condensing. The operating temperature of the LCD on the diagnostic display panel is +14 °F to +140 °F (-10 °C to +60 °C). All NQ SurgeLoc devices operate normally without reduction in performance when subjected to shock and vibrations described in IEC 60721-3-3, Class 3M4.

ENGLISH

Audible Noise

The device background noise is negligible and does not restrict the location of the installation.

Mounting

Refer to Figure 11 found on page 17 for typical mounting dimensions and weight.

Service Clearance

The service clearance should meet all applicable code requirements.

Equipment Performance

To obtain the maximum system performance, locate the device as close to the circuit being addressed as possible, to minimize the interconnecting wiring length. For every foot of wire length, approximately 160 Volts (6 kV / 3 kA, 8/20 microsecond) is added to the suppressed voltage. The Voltage Protection Rating (VPR) is located on the device nameplate and is measured six inches from the enclosure sidewall, according to UL® 1449 Third Edition.

Electrical

Voltage Rating

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

Confirm the Surge Protective Device voltage rating on the nameplate label is the same as the operating voltage.

Failure to follow these instructions will result in death or serious injury.

Prior to mounting the SPD, verify that the device has the same voltage rating as the power distribution system in which it is installed. Compare the nameplate voltage on the SPD with the nameplate of the electrical distribution equipment.

The specifier or user of the device must be familiar with the configuration and arrangement of the power distribution system in which any SPD is to be installed. The system configuration of any power distribution system is based strictly on how the secondary windings of the transformer supplying the service entrance main or load are configured. This includes whether or not the transformer windings are referenced to earth via a grounding conductor. The system configuration is not based on how any specific load or equipment is connected to a particular power distribution system. See Table 2 for the service voltage of each SPD.

Terminals, Wire Size, and Installation Torque

This SPD is designed to work in Square D™ Type NQ panelboards. Only panelboard bus screws should be used to connect the phase ring terminals to the bus bar.

Branch Circuit Overcurrent Protection

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARH FLASH

- Use conductors rated for the Overcurrent Protection Device (OCPD) per applicable codes.
- Use conductors rated for the application per applicable codes.

Failure to follow these instructions will result in death or serious injury.

UL 1449 Type 1 SPDs have been designed and approved for line side applications prior to the main service disconnect without supplemental overcurrent protection.

Type 1 SPDs can also be used in Type 2 applications (load side of OCPD). When either Type 1 or Type 2 SPDs are used on the load side, they must be installed per local codes.

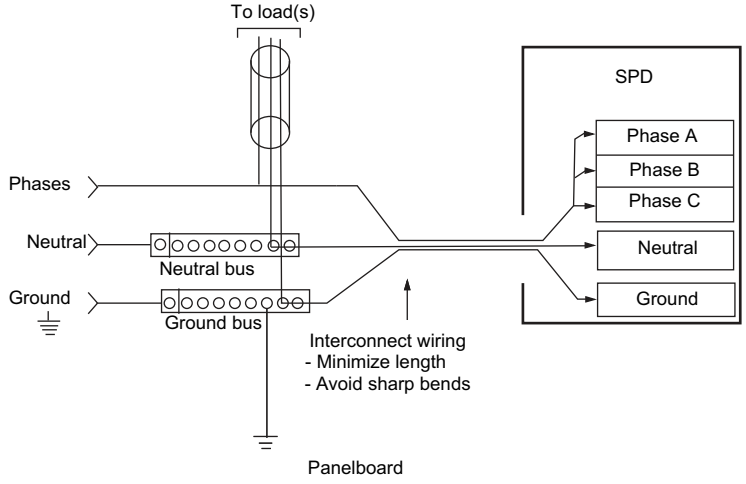
© 2014 Schneider Electric All Rights Reserved

For troubleshooting, call the Surgelogic Technical Assistance Group at 1-800-577-7353.

ENGLISH

Since the current drawn by the SPD device during standby operation is negligible, the SPD device can be connected to a dedicated, separate branch circuit or connected to a suitable existing branch circuit.

- When connecting to a separate, dedicated branch circuit, the OCPD setting must be selected to protect the conductors feeding the SPD device.
- When connecting to an existing branch circuit, the conductors connected to the SPD device must have an ampacity not less than the setting of the existing OCPD. (No larger than 30 A).



During overvoltage surge diversion, current will flow through the SPD device. The branch circuit OCPD must pass this current without tripping for the SPD device to function properly.

For further information concerning coordination of the OCPD with the SPD device, refer to Table 1.

Location of Surge Protective Device (SPD)

Locate the SPD as close as possible to the circuit being addressed to minimize the wire length and optimize SPD performance. Avoid long wire runs so that the device will perform as intended. Avoid sharp bends in the conductors. See Figure 1.

Figure 1: Surge Protective Device Wiring Practice

Grounding

⚠ WARNING

HAZARDOUS TOUCH VOLTAGE

- Connect the Surge Protective Device ground terminal to the building grounding grid structure.
- Use an appropriately sized equipment grounding conductor.
- Do not use a separate isolated ground for the NQ SurgeLoc Assembly device.
- Verify proper equipment connection to the grounding system.
- Verify ground grid continuity by performing regularly scheduled inspections. and testing as part of a comprehensive electrical maintenance program.

Failure to follow these instructions can result in death or serious injury.

© 2014 Schneider Electric All Rights Reserved

General

The NQ SPD has SPD elements connected from phase to ground. It is critical that there be a robust and effective connection to the building grounding structure. The grounding connection must utilize an equipment grounding conductor run with the phase and neutral (if present) connection of the power system. The SPD device should not be connected to a separate isolated ground.

For best overvoltage suppression by the NQ SPD, use a single-point ground system where the service entrance grounding electrode system is connected to and bonded to all other available electrodes, building steel, metal water pipes, driven rods, etc. (for reference, see IEEE 142-2007). The ground impedance measurement of the electrical system should be as low as possible, and in compliance with all applicable codes.

Solidly-Grounded Power Systems

NOTICE

SURGE PROTECTIVE DEVICE DAMAGE AND POWER SYSTEM OVERVOLTAGE

- Do not connect devices rated for use on solidly-grounded power systems to resistance-grounded (for example, High Resistance Ground) or ungrounded power systems.
- Verify that the service entrance equipment is bonded to ground in accordance with all applicable codes.
- Verify that the neutral terminal of the power system transformer feeding the device is bonded to system ground in accordance with all applicable codes.

Failure to follow these instructions can result in equipment damage.

SPDs rated for use on solidly-grounded power systems must not be connected to resistance-grounded (for example, HRG) or ungrounded power systems. Such a connection can result in damage to the SPD.

Always verify the power system grounding configuration prior to application of power to the device. Confirm that all ground bonds are installed at both the service entrance equipment and power system transformer prior to application of power.

Installation

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

UL Conditions of Acceptability

For use only in equipment where the acceptability of the combination is determined by Underwriters Laboratories®. When installed in the end-use equipment, the following are among the considerations to be made:

1. A suitable electrical enclosure shall be provided in the end-use product.
2. The device is intended for factory and field installations with the suitability of the connections (including spacing's between factory connectors) determined in the end-use application.
3. The Voltage Protection Rating (VPR) shall be determined in the end-product where applicable.
4. The SPD unit has been subjected to the following tests of UL 1449, 3rd Edition:
   a. Surge Testing (VPR)
   b. Nominal Discharge Current Test (20 kA)
   c. Dielectric Voltage Withstand
   d. Current Testing (200 kA Short Circuit Current, Intermediate Protective Devices (OCPD) or external enclosures.

SurgeLoc Assembly Installation

1. Turn off all power supplying this equipment before working on or inside any enclosure containing this equipment.
2. Confirm the SPD assembly has the same voltage rating and configuration as the system voltage and power system configuration to which it will be connected.
3. Remove panel door, dead front, and trim.
4. For best performance locate the SPD immediately adjacent to the main bus terminals. Note, keep ground and neutral wires as short as possible.
5. Facing the panel snap in mounting bracket, leading with the left edge of the SPD. Rotate the mounting bracket into place. See Figure 2.
6. Install four mounting screws provided. See Figure 3.

11. Connect the neutral wire to the neutral bus and the ground wire to the ground bus. For best performance keep wires as short as possible with no sharp bends.

    NOTE: This product will not work properly without neutral and ground connections.
12. Check that all connections are secure. Remove all tools and discarded hardware from the unit.
13. If necessary remove twelve (12) twist outs, six (6) per side, from the dead front to correlate with the SPD bezel.
14. Replace the deadfront, cover/door, and/or trim to the equipment.
15. Equipment may be re-energized after all of the above steps are complete.

SurgeLoc Assembly Removal

1. Turn off all power supplying this equipment before working on or inside any enclosure containing this equipment.
2. Remove any doors, trims, and the deadfront panel, per the panelboard instruction, so as to expose the SPD.
3. Loosen the locking nut by rotating it counter-clockwise until the nut reaches the latch screw head. Do not remove or loosen the latch screw. See Figure 10 and Figure 7 for part nomenclature. Pull the right side of the brick unit forward approximately 1/4 in. (7 mm) to release the sliding latch from the mount bracket slots.
4. Move the entire SPD to the left approximately 1/2 in. (13 mm) to release the fixed latch.
5. Remove the three phase screws to disconnect the three phase wires and secure the SPD.
6. Disconnect the ground and neutral wires.
7. Remove the SPD assembly.

Operation

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.
- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

LED Status Indicators

The SPD diagnostic display panel shows the status of each phase with green/red LEDs (see Figure 18). If the SPD is operating correctly, all of the phase LEDs will be illuminated green. If the LEDs are not illuminated in green follow the Troubleshooting flow chart, Figure 20.

Figure 18: MA Module LEDs

Audible Alarm

Push the alarm enable/disable button to enable or disable the alarm (see Figure 18). If the green alarm LED is lit the alarm is enabled. If the green alarm LED is not lit the alarm is disabled.

Surge Counter

The surge counter displays the number of transient voltage surges since the counter was last reset. To reset the surge counter press and hold the “Test” button for approximately 6 seconds.

Dry Contacts

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Use 600 Vac rated dry contact wiring.
- Dry contact wiring must have less than 1/16 in. (1.6 mm) exposed wire from the dry contact block.
- Maintain at least 1.0 in. (25 mm) separation between dry contact wiring and the power wiring in the enclosure.

Failure to follow these instructions will result in death or serious injury.

The NQ SurgeLoc series SPD comes equipped with dry contacts. The dry contacts are three-position, Form “C” type with Normally Open, Normally Closed, and Common connections.

In the unpowered state the contact is closed between terminals NC and COM. This is also the alarm condition. The opposite state, closed between terminals NO and COM, indicates that power is on to the unit and that no alarm condition exists (See Table 4).

These contacts can be used for remote indication of the SPD’s operating status to a computer interface board or emergency management system. Also, these contacts are designed to work with the SPD remote monitor option described in the next section.

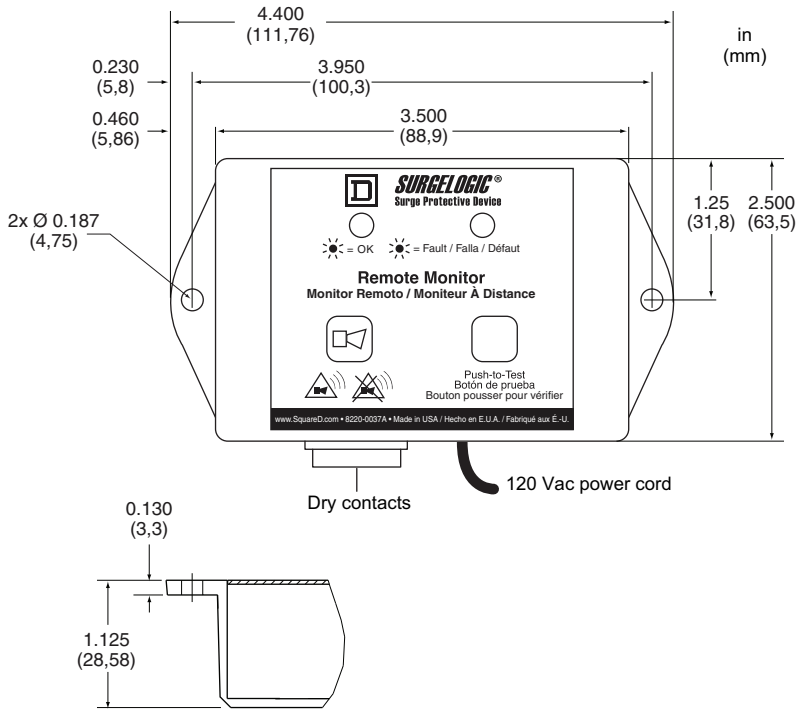
Table 4: Dry Contact Configuration

Alarm Contact Terminals	Contact State with Power Applied
NO to COM	Closed
NC to COM	Open

The dry contacts are designed for a maximum voltage of 250 Vac / 30 Vdc and a maximum current of 6 A. Minimum switching load is 10 mA at 5 Vdc. Higher energy applications may require additional relay implementation outside the SPD. Damage to the SPD relay caused by use with energy levels in excess of those discussed in this instruction bulletin are not covered by warranty. For application questions, contact the Surgelogic Technical Assistance Group at 1-800-577-7353.

Remote Monitor Option

The remote monitor option has two LEDs, one red and one green, and an audible alarm with an enable/disable switch. Normal status is a lit green LED, and no audible alarm. To test the integrity of the remote monitor, press the push-to-test switch. If the alarm is enabled, the green LED will turn off, the red LED will turn on, and the alarm will sound. Releasing the switch will complete the test; the red LED will turn off, the green LED will turn on and the alarm will shut off.



If suppression on any phase is lost, the green LED will turn off, the red LED will turn on and an alarm will sound. The audible alarm can be silenced by pushing the alarm enable/disable button. The alarm will silence and the green alarm LED will not be lit. The red LED will continue to be illuminated until the inoperative condition has been cleared.

The remote monitor includes a 120 Vac to 12 Vdc adapter with a six-foot power cord. Connections are made to the SPD diagnostic panel with Form “C”, 3-position dry contacts (provided) and the appropriate length of solid or stranded 22–14 AWG wire up to 1000 ft. (305 m) not provided.

Maintenance and Troubleshooting

⚠ DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E or CSA Z462.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.

- This equipment must be effectively grounded per all applicable codes. Use an equipment-grounding conductor to connect this equipment to the power system ground.

Failure to follow these instructions will result in death or serious injury.

Preventative Maintenance

Inspect the SPD periodically to maintain reliable system performance and continued transient voltage surge suppression. Periodically check the state of the diagnostic display panel LED status indicators. Routinely use the built-in diagnostics to inspect for inoperative modules.

Troubleshooting

If a module shows two green indicator lights and the display panel shows a red phase indicator light, follow the Troubleshooting Flow Chart in Figure 20.

HAZARDOUS VOLTAGE

Disconnect all power before working on equipment.

Electric shock will result in death or serious injury.

TENSION PELIGROSA

Desconecte toda la alimentación antes de efectuar cualquier trabajo en el equipo.

Las descargas eléctricas podrán causar la muerte o lesiones serias.

TENSION DANGEREUSE

Coupez toute l'alimentation avant de travailler sur cet appareil.

Une électrocution entraînera la mort ou des blessures graves.

SERIES

Series B applies only to the Type S, Form B starter (three ambient-compensated overloads). All parts of Form B, Series A and B starters are interchangeable; only the overload relay block differs. If replacing the overload relay block of a Form B, Series A starter with a Series B block, the overload relay

thermal units must be selected from the Series B tables for proper motor protection.

AUXILIARY CONTACTS

All contactors and starters feature a normally open (N.O.) holding circuit contact. N.O. or normally closed (N.C.) auxiliary contacts can be added in the field. Table 5 lists the Class and Type. Bulletin 30072-013-21 and the Square D Digest contain application information.

COVER-MOUNTED CONTROL UNITS

NEMA Type 1 general purpose enclosures with slip-on or hinged covers contain knockouts for field addition of the kits listed in Table 1.

OVERLOAD RELAYS

serie A con un bloque de la serie B, deberá seleccionar los elementos térmicos del relevador de sobrecarga de la tabla de selección de elementos térmicos de la serie B para proporcionar una protección adecuada al motor.

CONTACTOS AUXILIARES

Todos los contactores y arrancadores contienen un contacto de circuito de sostén normalmente abierto (N.A.). Los contactos auxiliares normalmente cerrados (N.C.) o N.A. se pueden instalar en el local del cliente. La tabla 5 enumera su clase y tipo. El boletín 30072-013-21 y el Digest de Square D contienen información sobre su aplicación.

UNIDADES DE CONTROL PARA MONTAJE EN LA CUBIERTA

Los gabinetes NEMA tipo 1 para uso general con cubiertas deslizantes o abisagradas contienen agujeros ciegos para la adición de los accesorios enumerados en la tabla 1 los cuales pueden ser instalados en el local del cliente.

RELEVADORES DE SOBRECARGA

CONTACTS AUXILIAIRES

Tous les contacteurs et démarreurs sont dotés d'un contact de circuit de retenue normalement ouvert (N.O.). Des contacts auxiliaires N.O. ou des contacts normalement fermés (N.F.) peuvent être ajoutés sur place. Le tableau 5 dresse la liste des classes et des types autorisés. Le bulletin 30072-013-21 et le Digest de Square D contiennent des renseignements relatifs aux applications.

UNITÉS DE COMMANDE MONTÉES SUR COUVERCLE

Les coffrets à usage général NEMA type 1 avec des couvercles à glissières ou à charnières contiennent des débouchures permettant l'ajout sur place des kits figurant au tableau 1.

RELAIS DE SURCHARGE

Standard

Relais de surcharge à fusion d'alliage : incorpore une ou trois unités thermiques. Son unité de contact (article 6, figure 1) est disponible avec un contact d'alarme isolé N.O. ou N.F. en plus du contact N.F. standard. L'unité

standard N.C. contact. The contact unit with alarm circuit contacts is field-installable (see Table 5).

Optional

Non-temperature compensated bimetallic overload relay: Form B1 incorporates two thermal units; Form B2 incorporates three thermal units.

Ambient-temperature compensated bimetallic overload relay (Form B): incorporates three thermal units.

SPDT contact (all Type S bimetallic overload relays): The N.O. contact can be used in an alarm circuit, and its wiring polarity must match that of the N.C. contact. Contacts are not replaceable. Use Table 5 to order replacement bimetallic overload relays.

Overload relays are not field-repairable. Do not disassemble them.

TERMINALS

*Use only **copper** wire* on device power and control terminals. Pressure wire power terminals are suitable for wire sizes 14–8 AWG (2.5–6 mm^2), solid or stranded. Pressure wire control terminals are suitable for wire sizes 16–12 AWG (1.5–4 mm^2), solid or stranded.

CONTACT INSPECTION AND REPLACEMENT

Discoloration and slight pitting do not harm contacts. ***Do not** file contacts*; this wastes contact material. Replace contacts (item 4 in Table 5) only when worn thin.

To inspect or replace contacts, disconnect all power. Do not remove any wiring. Loosen the two captive screws (C) holding the contact actuator to the contact block. Lift the contact actuator to expose the contacts.

estándar N.C. La unidad de contacto con los contactos de circuito de alarma se puede instalar en el local del cliente (vea la tabla 5).

Opcional

Relevador de sobrecarga bimetálico no compesado por temperatura: La forma B1 incorpora dos elementos térmicos; la forma B2 incorpora tres elementos térmicos.

Relevador de sobrecarga compensado por la temperatura ambiente (forma B): incorpora tres elementos térmicos.

Contacto 1P2T (todos los relevadores de sobrecarga bimetálicos tipo S): El contacto N.A. puede ser usado en un circuito de alarma y su polaridad de cableado debe corresponder con la polaridad del contacto N.C. Los contactos no se pueden reemplazar. Utilice la tabla 5 para solicitar repuestos de los relevadores de sobrecarga bimetálicos.

Los relavadores de sobrecarga no se pueden reparar en el local del cliente. No los desmonte.

TERMINALES

*Utilice sólo conductores de **cobre*** en las terminales de alimentación y control del dispositivo. Las terminales de alimentación de los conductores a presión son adecuadas para tamaños de cables calibre 14–8 (2,5–6 mm^2), sencillo o múltiple. Las terminales de control de los conductores a presión son adecuadas para tamaños de cables calibre 16–12 (1,5–4 mm^2), sencillo o múltiple.

INSPECCION Y REEMPLAZO DE CONTACTOS

La descoloración y picadura liviana no dañan los contactos. ***No** lime los contactos*; esto desperdicia el material del contacto. Reemplace los contactos (artículo 4 en la tabla 5) sólo cuando estén desgastados.

Para inspeccionar o reemplazar los contactos, desconecte toda la alimentación. No retire el cableado. Desatornille los dos tornillos imperdibles (C) sosteniendo el actuador de contacto

Relais de surcharge bimétallique non stabilisé en température : La forme B1 incorpore deux unités thermiques, la forme B2 incorpore trois unités thermiques.

Relais de surcharge bimétallique stabilisé en température (forme B) : incorpore trois unités thermiques.

Contact UPBD (tous les relais de surcharge bimétalliques de type S) : Le contact N.O. peut être utilisé dans un circuit d'alarme et la polarité de son câblage doit correspondre à celle du contact N.F. Les contacts ne peuvent pas être remplacés. Utiliser le tableau 5 pour commander des relais de surcharge bimétalliques de rechange.

Les relais de surcharge ne peuvent pas être réparés sur place. Ne pas les démonter.

BORNES

*Utiliser uniquement des fils de **cuivre*** sur les bornes d'alimentation et de commande du dispositif. Les bornes d'alimentation des fils à pression conviennent pour des fils de calibre 14–8 AWG (2,5 – 6 mm^2), à un ou plusieurs brins. Les bornes de commande des fils à pression conviennent pour des fils de calibre 16–12 AWG (1,5 – 4 mm^2), à un ou plusieurs brins.

INSPECTION ET REMPLACEMENT DES CONTACTS

La décoloration ou de légères piqûres de surface n'altèrent en rien les contacts. ***Ne pas** limer les contacts ;* ceci abîme le matériau du contact. Ne remplacer les contacts que lorsqu'ils sont usés (article 4, tableau 5).

Pour inspecter ou remplacer les contacts, mettre l'ensemble hors tension. Ne pas retirer le câblage. Desserrer les deux vis prisonnières (C) en maintenant l'actionneur de contact

MANUAL OPERATION

FUNCIONAMIENTO MANUAL

FONCTIONNEMENT MANUEL

⚠ WARNING / ADVERTENCIA / AVERTISSEMENT

UNINTENDED EQUIPMENT OPERATION

Disconnect all power before manually operating equipment to avoid contact arcing and unexpected load energization.

Failure to observe this precaution can result in death, serious injury, or equipment damage.

OPERACION INVOLUNTARIA DEL EQUIPO

Desconecte toda la alimentación antes de hacer funcionar manualmente el equipo, para evitar la formación de arcos en los contactos y la energización inesperada de carga.

El incumplimiento de esta precaución puede causar la muerte, lesiones serias o daños al equipo.

FONCTIONNEMENT INVOLONTAIRE DE L'APPAREIL

Coupez l'alimentation avant d'actionner manuellement cet appareil, pour éviter la formation d'arcs électriques sur les contacts ou une alimentation inattendue de la charge.

Si cette précaution n'est pas respectée, cela peut entraîner la mort, des blessures graves ou des dommages matériels.

Manually operate the contactor or starter with a screwdriver by pushing down the contact carrier. The coil cover has a slot for this use.

Haga funcionar manualmente el contactor o arrancador con un desarmador oprimiendo el portacontacto hacia abajo. La cubierta de la bobina tiene una ranura para este uso.

Actionner manuellement le contacteur ou le démarreur en poussant le porte-contact vers le bas avec un tournevis. Le couvercle de la bobine possède une fente réservée à cet usage.

COIL REPLACEMENT

To remove the coil, loosen the two captive cover screws (item A, Figure 1). Disconnect the wires from the coil terminals and remove the cover. Remove and disassemble the magnet, coil, and armature.

To replace the coil, first assemble the magnet, replacement coil, and armature. Manually operate the contact carrier (described in "Manual Operation") and insert the complete unit. Before installing the cover, manually operate the device to ensure that all parts function properly. Use the tightening torques listed in Table 2 when reassembling the device.

REEMPLAZO DE LA BOBINA

Para retirar la bobina, desatornille los dos tornillos imperdibles de la cubierta (artículo A en la figura 1). Desconecte los cables de las terminales de la bobina y quite la cubierta. Retire y desmonte la bobina, el imán y la armadura.

Para reemplazar la bobina, ensamble el imán, la bobina de repuesto y la armadura. Haga funcionar manualmente el portacontacto (descrito en "Funcionamiento manual") y coloque la unidad completa. Antes de instalar la cubierta, haga funcionar manualmente el dispositivo y asegúrese de que todos sus componentes estén funcionando adecuadamente. Utilice los pares de apriete enumerados en la tabla 2 cuando vuelva a montar el dispositivo.

REMPLACEMENT DE LA BOBINE

Pour retirer la bobine, desserrer les deux vis prisonnières du couvercle (article A, figure 1). Débrancher les fils des bornes de la bobine et ôter le couvercle. Enlever et démonter l'aimant, la bobine et l'armature.

Pour remplacer la bobine, assembler l'aimant, la bobine de rechange et l'armature. Actionner manuellement le porte-contact (comme décrit dans «Fonctionnement manuel») et insérer l'unité complète. Avant d'installer le couvercle, actionner manuellement le dispositif pour s'assurer que toutes les pièces fonctionnent correctement. Pour remonter le dispositif, utiliser les couples de serrage figurant au tableau 2.

Provide overcurrent protection for control circuits in accordance with the NEC and/or other applicable electrical codes. For applications requiring compliance with I.E.C. 947-5-1, use only Class CC fuses or better, 30 A maximum.

DISTANT CONTROL

Depending upon the voltage, wire size, and number of control wires used, series impedance or shunt capacitance may limit the maximum distance of the wire run for remotely operated contactors and starters. If distances to start or stop stations exceed those listed in Table 4, analyze the wire-run configuration and materials. For further information, request data bulletin M379 from D-FAX (document #1188), the Square D website (www.squared.com), or your local Square D field office.

Proporcione protección contra sobrecorriente en los circuitos de control de acuerdo con el NEC y/u otros códigos eléctricos aplicables. Utilice solamente fusibles clase CC o mejores, de 30 A como máximo, en las aplicaciones que requieran el cumplimiento de la norma 947-5-1 de I.E.C.

CONTROL A DISTANCIA

Dependiendo de la tensión, del calibre del conductor y de la cantidad de conductores de control que se usan, la impedancia en serie o la capacitancia en derivación puede limitar la distancia máxima del tendido de cables de contactores y arrancadores que se hacen funcionar remotamente. Si las distancias a las estaciones de arranque o parada exceden aquéllas enumeradas en la tabla 4, analice la configuración del tendido de cables y los materiales. Para obtener más información, solicite el boletín de datos del producto M379 de su oficina local de ventas de Square D.

Fournir un dispositif de protection contre la surcharge aux circuits de commande selon le CNÉ et d'autres codes électriques applicables. Pour les applications devant être conformes à la norme 947-5-1 de I.E.C. (CEI : Commission électronique internationale) utiliser uniquement les fusibles Classe CC ou supérieurs, de 30 A au maximum.

COMMANDE À DISTANCE

Selon la tension, le calibre du fil et le nombre de fils de commande utilisés, l'impédance de série ou la capacité shunt peut limiter la longeur maximale du câblage des contacteurs et des démarreurs commandés à distance. Si les distances aux postes de départ ou d'arrêt dépassent celles figurant dans le tableau 4, analyser la configuration et les matériaux du câblage des conducteurs. Pour de plus amples informations, consulter le bulletin M379 sur les données des produits, auprès du bureau local de ventes de Square D.

PARTS ORDERING

Specify the quantity, the part number or Class and Type, and the part description, giving complete nameplate data of the device (e.g., one armature and magnet kit 31041-605-50 for a Class 8536, Type SCO3, Series A starter).

SOLICITUD DE PIEZAS

Especifique la cantidad, el número de pieza o clase y tipo, y descripción de la pieza, proporcionando los datos completos de la placa de identificación del dispositivo (p.ej., un accesorio de imán y armadura 31041-605-50 para un arrancador clase 8536, tipo SCO3, serie A).

COMMANDE DE PIÈCES

Spécifier la quantité, le numéro de pièce ou la classe et le type, ainsi que la description de la pièce, en donnant tous les renseignements figurant sur la plaque signalétique du dispositif (par ex., kit d'armature et d'aimant 31041-605-50 pour un démarreur de classe 8536, type SCO3, série A).

⚠ DANGER / PELIGRO / DANGER

HAZARDOUS VOLTAGE

Disconnect all power before working on equipment.

Failure to follow this instruction will result in death or serious injury.

TENSION PELIGROSA

Desconecte toda la alimentación antes de efectuar cualquier trabajo en el equipo.

El incumplimiento de esta precaución podrá causar la muerte o lesiones serias.

TENSION DANGEREUSE

Coupez l'alimentation avant de travailler sur cet appareil.

Si cette précaution n'est pas respectée, cela entraînera la mort ou des blessures graves.

CONTACT ACTUATOR

Movable contacts are operated by a push button or toggle operator.

ACTUADOR DE CONTACTOS

Los contactos móviles son activados por un operador, tipo botón pulsador o articulado.

ACTIONNEUR DE CONTACTS

Les contacts mobiles sont activés par un opérateur de type bouton-poussoir ou à bascule.

CONTACT INSPECTION

Loosen the two captive screws (A) holding the contact actuator mechanism to the contact block. Lift the contact actuator to expose the contacts.

INSPECCION DE CONTACTOS

Afloje los dos tornillos cautivos (A) sujetando el mecanismo del actuador de contactos contra el bloque de contactos. Levante el actuador de contactos para mostrar los contactos.

INSPECTION DES CONTACTS

Desserrer les deux vis imperdables (A) retenant le mécanisme de l'actionneur de contacts contre le bloc de contacts. Soulever l'actionneur pour exposer les contacts.

Discoloration and slight pitting do not harm silver alloy contacts. **Do not file contacts**; this wastes contact material. Replace contacts only when worn thin. Table 5 lists replacement parts.

CONTACT REPLACEMENTS

See Figure 1. To replace the contacts, loosen the two captive screws (A) and remove the contact actuator. Remove the movable contacts (1) from the yoke bar by compressing the contact spring and sliding the contact sideways. Change the contact springs before inserting new movable contacts. Remove the stationary contacts by loosening the contact mounting screws (B and C). Reassemble in reverse order.

WIRING

Use only copper wire on device power and control terminals.

OVERLOAD RELAYS

Standard: *Melting alloy thermal overload relays:* incorporate one or three thermal units. (Three-phase manual starters manufactured before mid-1972 had a shorting strap installed in the center leg of the overload relay. To convert these devices from two to three thermal units, remove the shorting strap and install a third thermal unit.)

NOTE: Thermal units must be installed and the device reset before starter contacts will operate. Install thermal units so the type designation can be read and with the pawl (item 5) above the ratchet wheel as shown in Figure 1.

Continued overcurrent through the thermal unit raises its temperature,

La decoloración y picaduras moderadas no dañan los contactos de aleación de plata. **No lime los contactos;** esto degasta el material del contacto. Reemplace los contactos sólo una vez que estén desgastados. La tabla 5 lista las piezas de repuesto.

REEMPLAZO DE CONTACTOS

Vea la figura 1. Para reemplazar los contactos, afloje los dos tornillos cautivos (A) y retire el actuador de contactos. Para retirar los contactos móviles (1) del yugo, comprima el resorte del contacto y deslice el contacto lateralmente. Cambie los resortes de los contactos antes de insertar los nuevos contactos móviles. Para retirar los contactos fijos, afloje los tornillos de montaje (B y C) de los contactos. Vuelva a montarlos en el orden inverso al de su instalación .

CABLEADO

Utilice conductores de cobre solamente en las terminales de alimentación y control del dispositivo.

RELEVADORES DE SOBRECARGA

Estándar: *Relevadores de sobrecarga térmica de aleación fusible:* incorporan uno ó tres elementos térmicos. (Los arrancadores manuales de tres fases fabricados en la primera mitad de 1972 tenían una cinta cortocircuitadora instalada en la parte central del relevador de sobrecarga. Para convertir estos dispositivos de dos a tres elementos térmicos, retire la cinta cortocircuitadora e instale un tercer elemento térmico.)

NOTA: Es necesario instalar los elementos térmicos y restablecer el dispositivo antes de que los contactos del arrancador funcionen. Instale los elementos térmicos para que se pueda leer la designación de tipo y para que el trinquete (artículo 5) quede sobre la rueda dentada como se muestra en la figura 1.

La presencia de sobrecorriente continua en los elementos térmicos

La décoloration ou les légères piqûres de surface n'altèrent en rien les contacts à alliage d'argent. **Ne pas limer les contacts**; cela abîme le matériau des contacts. Remplacer les contacts seulement lorsqu'ils sont usés. Le tableau 5 donne la liste des pièces de rechange.

REMPLACEMENT DES CONTACTS

Voir la figure 1. Pour remplacer les contacts, desserrer les deux vis imperdables (A) et enlever l'actionneur de contacts. Retirer les contacts mobiles (1) de la barre de l'étrier en serrant le ressort du contact et en faisant glisser ce dernier latéralement. Remplacer les ressorts des contacts avant d'insérer les contacts mobiles neufs. Retirer les contacts fixes en desserrant les vis de montage (B et C). Les remonter dans l'ordre inverse.

CÂBLAGE

Utiliser seulement des fils en cuivre avec les bornes d'alimentation et de commande du dispositif.

RELAIS DE SURCHARGE

Standard : *Relais de surchage thermique à fusion d'alliage :* comprennent de une ou trois unités thermiques. (Les démarreurs manuels triphasés fabriqués avant la mi–1972 avaient une bande de court-circuit installée dans la branche centrale du relais de surcharge. Pour convertir les dispositifs à deux unités thermiques en dispositifs à trois unités, retirer la bande de court-circuit et installer une troisième unité thermique.)

REMARQUE : Pour que les contacts du démarreur soient fonctionnels les unités thermiques doivent être installées et le dispositif doit être réinitialisé. Installer les unités thermiques en s'assurant que l'indication du type est lisible et que le crochet (article 5) reste sur la roue à rochet conformément à la figure 1.

Une surintensité continue dans l'unité thermique élève la température et

melting the alloy in its solder pot, allowing the ratchet wheel to rotate. This releases the overload relay pawl assembly, allowing the toggle spring to retract the contacts. This action also centers the push button or toggle operator, indicating the starter is tripped.

*NOTE: Before resetting the relay, allow one to two minutes for the alloy to solidify. **Do not** disassemble the overload relay block because motor protection could be disabled, possibly damaging equipment.*

ELECTRICAL INTERLOCKS (FORM X)

One internal interlock (item 3), either normally open (N.O.) or normally closed (N.C.), can be added to all manual starters. It occupies either the upper right-hand or left-hand corner of the device, and is field installable. Table 1 lists location and replacement part numbers for Class 2510 starter interlocks. Table 5 lists replacement parts.

eleva su temperatura lo cual funde la aleación en su depósito para soldadura y permite la rotación de la rueda dentada. Esto libera el ensamble del trinquete del relevador de sobrecarga, y permite que el resorte articulado retire los contactos. Esta acción también centra el botón pulsador u operador articulado, lo cual indica que se ha disparado el arrancador.

*NOTA: Antes de restablecer el relevador, deje pasar de uno a dos minutos para que se solidifique la aleación. **No** desmonte el bloque del relevador de sobrecarga ya que puede inhabilitar la protección del motor y posiblemente dañar el equipo.*

ENTRELACES ELECTRICOS (FORMA X)

Es posible agregar un entrelace interno (artículo 3), o normalmente abierto (N.A.) o normalmente cerrado (N.C.) a todos los arrancadores manuales. Este se coloca en la esquina superior derecha o izquierda del dispositivo y puede ser instalado en campo. La tabla 1 lista la ubicación y los números de las piezas de repuesto de los entrelaces de los arrancadores clase 2510. La tabla 5 lista las piezas de repuesto.

provoque la fusion de l'alliage dans le pot à souder, entraînant la rotation de la roue à rochet. Ceci libère l'assemblage du crochet du relais de surchage, permettant au ressort de la bascule de retirer les contacts. Cette action centre également le bouton-poussoir ou l'opérateur à bascule, indiquant que le démarreur est déclenché.

*REMARQUE : Avant de réarmer le relais, attendre une ou deux minutes que l'alliage se solidifie. **Ne pas** démonter le bloc de relais de surcharge car la protection du moteur serait désactivée et l'appareil pourrait être endommagé.*

INTERVERROUILLAGES ÉLECTRIQUES (FORME X)

Un interverrouillage interne (article 3), soit normalement ouvert (N.O.) ou normalement fermé (N.F.) peut être ajouté à tous les démarreurs manuels. Il est situé sur le coin supérieur droit ou gauche du dispositif et s'installe sur place. Le tableau 1 donne la liste des emplacements et des numéros des pièces de rechange des interverrouillages pour démarreurs de classe 2510. Le tableau 5 contient les pièces de rechange.

LOCK OFF MECHANISM

The starter can be locked only in the OFF position, by lifting the metal tab with the lock symbol on the contact actuator and placing a padlock through the hole in this tab. In the ON position, withdrawing the lock tab opens the contacts of the device.

MECANISMO DE BLOQUEO

El arrancador puede ser bloqueado solamente en la posición de desconectado (O), levantando la lengüeta de metal con el símbolo de candado en el actuador de contactos y colocando un candado a través del agujero en esta lengüeta. En la posición de conectado (|), se abren los contactos del dispositivo al retirar la lengüeta de bloqueo.

MÉCANISME DE VERROUILLAGE

Le démarreur ne peut être verrouillé que dans la position d'arrêt (O), en soulevant la languette métallique avec le symbole de cadenas sur l'actionneur de contacts et en faisant passer un cadenas par le trou de cette languette. Dans la position de marche (|), le retrait de la languette de blocage ouvre les contacts du dispositif.

PILOT LIGHT KIT (FORM P11)

A red pilot light usable on any voltage (110-600 V) may be factory installed. Kits may be field installed in the cover of Type 1 surface- and flush-mounting enclosures. Table 2 lists kits for field modification.

ACCESORIO DE LAMPARA PILOTO (FORMA P11)

Una lámpara piloto roja utilizable bajo cualquier tensión (110-600 V ~) puede haber sido instalada en la fábrica. Los accesorios pueden ser instalados en campo en la cubierta de los gabinetes de montaje para sobreponer o empotrar tipo 1. La tabla 2 lista los accesorios para la modificación en campo.

KIT DE LAMPE TÉMOIN (FORME P11)

Une lampe témoin rouge utilisable à toutes les tensions (110 à 600 V) peut avoir été installée en usine. Les kits peuvent être installés sur place dans le couvercle des coffrets type 1 montés en surface ou encastrés. Le tableau 2 contient la liste des kits à installer sur place.

Replacement interiors for Class 2510 NEMA 1 surface- and flush-mounted enclosures are available with either push button or toggle operation. Catalog 2510CT9701 and the Square D Digest list open-type replacement starters.

INTERIORES DE REPUESTO

Las interiores de repuesto se encuentran disponibles para gabinetes sobrepuestos y empotrados NEMA tipo 1 clase 2510 con un operador articulado o de botón pulsador. El catálogo 2510CT9701 y el compendiado de Square D listan los arrancadores de repuesto de tipo abierto.

INTÉRIEURS DE RECHANGE

Les intérieurs de rechange pour les coffrets NEMA type 1 classe 2510 montés en surface et encastrés sont disponibles avec un opérateur à bouton-poussoir ou à bascule. Le catalogue 2510CT9701 et le Digest Square D contiennent la liste des démarreurs de rechange de type ouvert.

MANUAL STARTERS CLASS 2511/2512

Class 2511 (reversing) and 2512 (two-speed) manual starters are mechanically interlocked through an interference-type mechanism, part number 31085-070-01. It mounts between the starters and engages the movable contact carriers. Since Classes 2511 and 2512 use a special contact actuator, the standard Class 2510 starter cannot be used for replacement. If either unit (right-hand or left-hand) needs replacement, order a complete starter (see Table 4).

ARRANCADORES MANUALES CLASE 2511/2512

Los arrancadores manuales clase 2511 (reversibles) y 2512 (de dos velocidades) están entrelazados mecánicamente a través de un mecanismo de interposición, número de pieza 31085-070-01 que se monta entre los arrancadores y engancha los portacontactos móviles. Puesto que las clases 2511 y 2512 utilzan un actuador especial de contactos, el arrancador clase 2510 no se puede utilizar como repuesto. Si cualquiera de las unidades (derecha o izquierda) tiene que ser reemplazada, solicite un arrancador completo (vea la tabla 4).

DÉMARREURS MANUELS CLASSE 2511/2512

Les démarreurs manuels classe 2511 (inversibles) et ceux de classe 2512 (à deux vitesses) sont mécaniquement interverrouillés par un mécanisme de serrage, nº de pièce 31085-070-01. Il se monte entre les démarreurs et engage les porte-contacts mobiles. Comme les démarreurs classes 2511 et 2512 utilisent un actionneur de contacts spécial, le démarreur classe 2510 ne peut pas être utilisé comme démarreur de rechange. Pour remplacer une unité (de droite ou de gauche), commander un démarreur complet (voir le tableau 4).

SHORT-CIRCUIT PROTECTION

Provide branch-circuit overcurrent protection for each contactor or starter. For contactors, provide branch circuit overcurrent protection in accordance with the National Electrical Code and local electrical codes. For starters, refer to instructions furnished with the thermal unit selection table.

PROTECCION CONTRA CORTOCIRCUITO

Proporcione protección contra sobrecorriente en los circuitos en derivación a cada uno de los contactores o arrancadores. Proporcione la protección contra sobrecorriente en los circuitos en derivación a los contactores de acuerdo con el código nacional eléctrico de EUA (NEA) y/o con los códigos eléctricos locales. Para los arrancadores, consulte las instrucciones provistas con la tabla de selección del elemento térmico.

PROTECTION CONTRE LES COURTS-CIRCUITS

Fournir une protection contre la surintensité des circuits d'artère pour chaque contacteur ou démarreur. Fournir aux contacteurs la protection contre la surintensité des circuits d'artère conformément au Code national de l'électricité (CNÉ) et aux normes locales de l'électricité. Pour les démarreurs, se reporter aux directives fournies avec le tableau de sélection de l'unité thermique.

ASSEMBLY

Table 6 and the device instruction sheet provide factory recommended tightening torques for mechanical, electrical and pressure wire connections. Follow these torques to ensure proper functioning of the device. If the contact actuator is removed for contact inspection or replacement, reset the device after reassembly.

MONTAJE

La tabla 6 y la hoja de instrucciones del dispositivo proporcionan los pares de apriete recomendados de fábrica para las conexiones mecánicas, eléctricas y del conductor de presión. Utilice estos pares de apriete para asegurar el funcionamiento adecuado del dispositivo. Si se retira el actuador de contactos para realizar una inspección o reemplazo de los contactos, restablezca el dispositivo después de volverlo a montar.

ASSEMBLAGE

Le tableau 6 et la feuille de directives du dispositif donnent les couples de serrage recommandés pour les raccordements mécaniques, électriques et du fil à pression. Respecter ces couples de serrage pour assurer un fonctionnement correct du dispositif. Si l'actionneur de contacts est enlevé pour l'inspection ou le remplacement des contacts, réarmer le dispositif après le remontage.

PARTS ORDERING

Specify the quantity, part number and description of the part, giving complete nameplate data of the device; e.g., 1 contact kit Class 9998 Type ML2 for Class 2510 Type MCG3, Series A manual starter.

SOLICITUD DE PIEZAS

Especifique la cantidad, número y descripción de la pieza, proporcionando los datos completos de la placa de identificación del dispositivo; por ejemplo, 1 accesorio de contactos clase 9998 tipo ML2 para arrancador manual serie A clase 2510 tipo MCG3.

COMMANDES DE PIÈCES

Spécifier la quantité, le numéro de pièce et la description de la pièce en donnant toutes les données de la plaque d'identification du dispositif (par ex., 1 kit de contact classe 9998 type ML2 pour démarreur manuel série A, classe 2510 type MCG3).

INTRODUCTION

Safety switches are properly lubricated at the factory. However, periodic cleaning and lubrication may be required. The maintenance interval between lubrications depends on the amount of switch usage and the ambient operating conditions. The maximum maintenance interval should not exceed one year for mechanical or current-carrying parts.

For additional information, refer to publication NFPA-70B, “Recommended Practice for Electrical Equipment Maintenance”.

Unusual Performance Conditions

Contact Square D for information regarding performance under unusual conditions. Examples of unusual conditions are shown in Table 1 below:

INTRODUCCIÓN

Los interruptores de seguridad han sido lubricados correctamente en la fábrica; sin embargo, es necesario realizar limpieza y lubricación periódicamente. El intervalo de servicio de mantenimiento entre lubricaciones depende del uso del interruptor y de las condiciones ambientales de funcionamiento. El intervalo de servicio de mantenimiento máximo no debe exceder un año para las piezas mecánicas o conductoras de corriente.

Si desea obtener información adicional, consulte la publicación NFPA-70B, “Recomended Practice for Electrical Equipment Maintenance” (prácticas recomendadas de servicio de mantenimiento para el equipo eléctrico).

Condiciones de funcionamiento poco comunes

Póngase en contacto con Square D para obtener información con respecto al funcionamiento de este equipo bajo condiciones poco comunes. La tabla 1 muestra ejemplos de condiciones poco comunes:

INTRODUCTION

Les interrupteurs de sécurité sont lubrifiés de façon appropriée à l'usine. Toutefois, un nettoyage et une lubrification périodiques peuvent être nécessaires. L'intervalle d'entretien entre les lubrifications dépend de la fréquence d'utilisation de l'interrupteur et des conditions ambiantes de fonctionnement. L'intervalle d'entretien maximum ne doit pas dépasser un an pour les pièces mécaniques ou porteuses de courant.

Pour avoir d'autres renseignements, se reporter à la publication NFPA-70B, « Recommended Practice for Electrical Equipment Maintenance » (Pratique recommandée pour l'entretien des appareils électriques).

⚠ DANGER / PELIGRO / DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Never operate energized switch with door open.
- Turn off switch before removing or installing fuses or making load side connections.
- Always use a properly rated voltage sensing device at all line and load fuse clips to confirm switch is off.
- Turn off power supplying switch before doing any other work on or inside switch.
- Do not use renewable link fuses in fused switches.

Failure to follow these instructions will result in death or serious injury.

PELIGRO DE DESCARGA ELÉCTRICA, EXPLOSIÓN O DESTELLO POR ARQUEO

- Utilice equipo de protección personal (EPP) apropiado y siga las prácticas de seguridad eléctrica establecidas por su Compañía, consulte la norma 70E de NFPA.
- Solamente el personal eléctrico especializado deberá instalar y prestar servicio de mantenimiento a este equipo.
- Nunca haga funcionar el interruptor energizado con la puerta abierta.
- Desconecte el interruptor antes de retirar o instalar los fusibles o realizar las conexiones del lado de carga.
- Siempre utilice un dispositivo detector de tensión nominal adecuado en todos los clips para fusibles en los lados de línea y carga para confirmar la desenergización del interruptor.
- Desenergice el interruptor antes de realizar cualquier otro trabajo dentro o fuera de él.
- No use fusibles renovables en los interruptores fusibles.

El incumplimiento de estas instrucciones podrá causar la muerte o lesiones serias.

RISQUE D'ÉLECTROCUTION, D'EXPLOSION OU D'ÉCLAIR D'ARC

- Portez un équipement de protection personnelle (ÉPP) approprié et observez les méthodes de travail électrique sécuritaire. Voir NFPA 70E.
- Seul un personnel qualifié doit effectuer l'installation et l'entretien de cet appareil.
- Ne faites jamais fonctionner l'interrupteur sous tension avec la porte ouverte.
- Mettez L'inerrupteur hors tension avant d'enlever ou d'installer des fusibles ou de faire des faccordements sur le côté charge.
- Utilisez toujours un dispositif de détection de tension ayant une valeur nominale appropriée sur tous les porte-fusibles du côté ligne et charge pour s'assurer que l'interrupteur soit hors tension.
- Coupez l'alimentation de l'interrupteur avant d'y faire tout autre travail.
- N'utilisez pas de fusibles renouvelables dans les interrupteurs à fusibles..

Si ces directives ne sont pas respectées, cela entraînera la mort ou des blessures graves.

ANNUAL MAINTENANCE PROCEDURES

1. Turn off power supplying the switch before performing any work on or inside the switch.
2. Open the switch blades by moving the operating handle to the OFF (**O**) position.
3. Lock out or tag the switch, per local procedures.
4. Open the enclosure door.
5. Always use a properly rated voltage sensing device at all line and load-side lugs (teminals) to confirm power is off.

   NOTE: Do not remove any parts from the switch or operating mechanism unless specifically instructed to do so in the following procedures. Vacuum any loose material from inside the switch. Wipe internal parts and the inside of the enclosure with a damp, lint-free cloth.
6. Visually inspect the switch for loose parts or hardware:

   a. Retighten the hardware as needed. Refer to the wiring diagram.
   b. Do not re-energize the switch if any worn or damaged parts are found. Replace them before re-energizing the switch.

PROCEDIMIENTOS DE SERVICIOS DE MANTENIMIENTO ANUALES

1. Desenergice el interruptor antes de realizar cualquier trabajo dentro o fuera de él.
2. Abra las cuchillas del interruptor moviendo la palanca de funcionamiento a la posición de abierto (**O**).
3. Bloquee o etiquete el interruptor de acuerdo con los procedimientos locales.
4. Abra la puerta del gabinete.
5. Siempre utilice un dispositivo detector de tensión nominal adecuado en todas las zapatas (terminales) del lado de línea y carga para confirmar la desenergización del equipo.

   NOTA: No retire ninguna pieza del interruptor ni del mecanismo de funcionamiento a no ser que se le indique eso específicamente en los siguientes procedimientos. Aspire el material suelto que se encuentra dentro del interruptor. Limpie las piezas internas y el interior del gabinete con una tela húmeda sin pelusas.
6. Realice una inspección visual al interruptor para ver si encuentra piezas o herrajes sueltos:

   a. Vuelva a apretar los herrajes a medida que sea necesario. Consulte el diagrama de cableado.
   b. No vuelva a energizar el interruptor si encuentra piezas desgastadas o dañadas; sustitúyalas antes de volver a energizar el interruptor.

PROCÉDURES D'ENTRETIEN ANNUEL

1. Couper l'alimentation de l'interrupteur avant d'effectuer tout travail sur ou à l'intérieur de l'interrupteur.
2. Ouvrir les lames de l'interrupteur en plaçant la manette de fonctionnement sur la position d'ARRÊT (**O**).
3. Verrouiller ou étiqueter l'interrupteur, selon les procédures locales.
4. Ouvrir la porte du coffret.
5. Toujours utiliser un dispositif de détection de tension à valeur nominale appropriée sur toutes les cosses (bornes) du côté ligne et charge pour s'assurer que l'interrupteur est hors tension.

   REMARQUE : Ne retirer aucune pièce de l'interrupteur ou du mécanisme de fonctionnement sauf en cas d'instruction précise de le faire dans les procédures suivantes. Évacuer à l'aspirateur tous corps étrangers se trouvant à l'intérieur de l'interrupteur. Essuyer les pièces internes et l'intérieur du coffret à l'aide d'un chiffon mouillé, non pelucheux.
6. Inspecter visuellement l'interrupteur pour voir s'il y a des pièces ou de la quincaillerie désserrée :

   a. Resserrer la quincaillerie au besoin. Se reporter au schéma de câblage.
   b. Ne pas remettre l'interrupteur sous tension en présence de pièces usées ou abîmées. Les remplacer avant de remettre l'interrupteur sous tension.

Parts Removal

1. Remove the arc supressor(s) or arc shield(s) from the switches by loosening the fastener(s) holding the suppressor(s) / shield(s) in place. See Figures 1 and 2.

Desmontaje de piezas

1. Retire el o los supresores o protectores de arco de los interruptores aflojando los sujetadores que los sostienen en su lugar. Vea las figuras 1 y 2.

Démontage des pièces

1. Retirer le ou les suppresseurs ou blindages d'arc des interrupteurs en desserrant les attaches qui les maintiennent en place. Voir les figures 1 et 2.

CAUTION / PRECAUCIÓN / ATTENTION

HAZARD OF EQUIPMENT DAMAGE

Do not disassemble the switch line base assembly or remove the blade rotor when cleaning the line-side jaw or the switch blade. See Figure 3 on page 4.

Failure to follow this instruction can result in equipment damage.

PELIGRO DE DAÑO AL EQUIPO

No desmonte el ensamble de la base de línea del interruptor o retire el rotor de cuchilla al limpiar la mordaza del lado de línea o la cuchilla del interruptor, vea la figura 3 en la página 4.

El incumplimiento de esta instrucción puede causar daño al equipo.

RISQUE DE DOMMAGES MATÉRIELS

Ne démontez pas l'assemblage de la base de ligne de l'interrupteur ou ne retirez pas le rotor à lame lorsque vous nettoyez la mâchoire côté ligne ou la lame de l'interrupteur. Voir la figure 3 à la page 4.

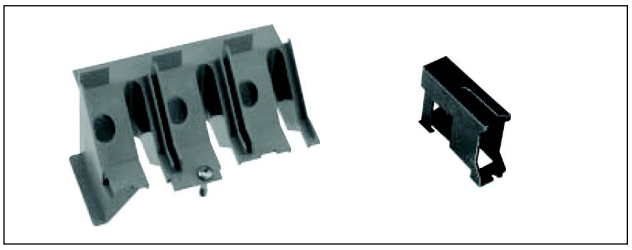
Si cette précaution n'est pas respectée, cela peut entraîner des dommages matériels.

2. Remove old grease and other contaminants from the line-side jaws and switchblades with a clean, lint-free cloth. If the lubricant has dried, remove it with CRC®-type HF Contact Cleaner, or equivalent, sprayed on a cloth.
3. Relubricate the cleaned areas with a thin film of Dow Corning® BG20 grease only.

   NOTE: Do not substitute any other lubricant. Other lubricants may not be suitable for electrical applications and could alter the performance of the switch. Dow Corning BG20 is available from Square D (part number SWLUB).
4. Exercise the operating mechanism to ensure proper operation by opening and closing the switch five times with the door closed. Open the switch blades.

2. Retire la grasa vieja y otros contaminantes de la mordaza del lado de línea y cuchillas del interruptor con una tela limpia sin pelusas. Si el lubricante se ha secado, retírelo con un limpiador de contacto CRC® tipo HF o uno equivalente, rociado en un pedazo de tela.
3. Vuelva a lubricar las áreas limpiadas con una capa delgada de grasa Dow Corning® BG20 solamente.

   NOTA: No utilice otro tipo de lubricante; es posible que no sean adecuados para aplicaciones eléctricas y pueden alterar el funcionamiento del interruptor. La grasa Dow Corning BG20 se encuentra disponible de Square D (número de pieza SWLUB).
4. Realice una prueba al mecanismo de funcionamiento y asegúrese de que funciona correctamente abriendo y cerrando el interruptor cinco veces con la puerta cerrada. Abra las cuchillas del interruptor.



2. Retirer toute graisse ancienne et autres polluants des mâchoires côté ligne et des lames de l'interrupteur à l'aide d'un chiffon propre et non pelucheux. Si le lubrifiant a séché, l'enlever avec un nettoyant pour contact CRC® de type HF ou l'équivalent, vaporisé sur un chiffon.
3. Relubrifier les zones propres avec une fine pellicule de graisse Dow Corning® BG20 uniquement.

   REMARQUE : Ne substituer aucun autre lubrifiant. D'autres lubrifiants pourraient ne pas convenir pour des applications électriques et pourraient altérer le fonctionnement de l'interrupteur. Le Dow Corning BG20 est disponible chez Square D (n° de pièce SWLUB).
4. Manœuvrer le mécanisme de fonctionnement pour s'assurer qu'il fonctionne correctement, en ouvrant et fermant l'interrupteur cinq fois avec la porte fermée. Ouvrir les lames de l'interrupteur.

Parts Replacement

1. Reinstall the arc suppressor(s) or arc shield(s) according to the torque values in Table 2.
2. Ensure that the two insulating plugs in each phase (400–1200 A only) are firmly seated. See Figure 4.

Colocación de piezas

1. Vuelva a instalar el o los supresores o protectores de arco de acuerdo con los valores de par de apriete mostrados en la tabla 2.
2. Asegúrese de que los dos enchufes de aislamiento en cada fase (de 400 a 1 200 A solamente) estén bien apoyados, vea la figura 4.

Remise en place des pièces

1. Réinstaller le ou les suppresseurs ou blindages d'arc conformément aux valeurs de couple indiquées au tableau 2.
2. S'assurer que les deux fiches isolantes de chaque phase (400 à 1 200 A seulement) sont bien en place. Voir la figure 4.

RE-ENERGIZE THE SWITCH

1. Close and latch the door.
2. Turn off all downstream loads.
3. Turn on power supplying the switch.
4. Turn on the switch.
5. Turn on all downstream loads.

RE-ENERGIZACIÓN DEL INTERRUPTOR

1. Cierre y ponga seguro a la puerta.
2. Desconecte todas las cargas descendentes.
3. Energice el interruptor.
4. Coloque el interruptor en la posición de cerrado (I).
5. Conecte todas las cargas descendentes.

REMISE DE L'INTERRUPTEUR SOUS TENSION

1. Fermer la porte de l'interrupteur.
2. Mettre hors tension toutes les charges en aval.
3. Mettre l'interrupteur sous tension.
4. Mettre l'interrupteur en position de marche (I).
5. Mettre sous tension toutes les charges en aval.

⚠ DANGER / PELIGRO / DANGER

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

PELIGRO DE DESCARGA ELÉCTRICA, EXPLOSIÓN O DESTELLO POR ARQUEO

- Utilice equipo de protección personal (EPP) apropiado y siga las prácticas de seguridad eléctrica establecidas por su Compañía (consulte la norma NFPA 70E).
- Solamente el personal eléctrico especializado deberá instalar y prestar servicio de mantenimiento a este equipo.
- Desenergice el equipo antes de realizar cualquier trabajo en él.
- Siempre utilice un dispositivo detector de tensión nominal adecuado para confirmar la desenergización del equipo.
- Vuelva a colocar todos los dispositivos, las puertas y las cubiertas antes de volver a energizar el equipo.

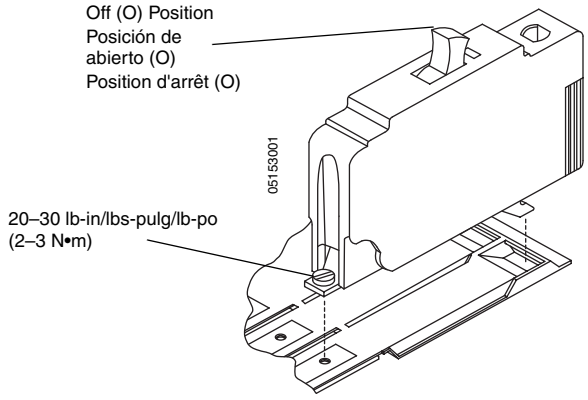
El incumplimiento de estas instrucciones podrá causar la muerte o lesiones serias.

RISQUE D'ELECTROCUTION, D'EXPLOSION OU D'ECLAIR D'ARC

- Portez un équipement de protection personnel (ÉPP) approprié et observez les méthodes de travail électrique sécuritaire. Voir NFPA 70E.
- Seul un personnel qualifié doit effectuer l'installation et l'entretien de cet appareil.
- Coupez l'alimentation de l'appareil avant d'y travailler.
- Utilisez toujours un dispositif de détection de tension à valeur nominale appropriée pour s'assurer que l'alimentation est coupée.
- Replacez tous les dispositifs, les portes et les couvercles avant de mettre l'appareil sous tension.

Si ces précautions ne sont pas respectées, cela entraînera la mort ou des blessures graves.

CIRCUIT BREAKER INSTALLATION



Turn off all power supplying this equipment before working on or inside equipment. Turn off circuit breaker.

INSTALACIÓN DEL INTERRUPTOR AUTOMÁTICO

Desenergice el equipo antes de realizar cualquier trabajo en él. Desconectar interruptor automático.

INSTALLATION DU DISJONCTEUR

Couper l'alimentation de l'appareil avant d'y travailler. Couper l'alimentation à disjoncteur.

WIRE INSTALLATION

INSTALACIÓN DE CABLES

INSTALLATION DES CÂBLES

CAUTION / PRECAUCIÓN / ATTENTION

HAZARD OF EQUIPMENT DAMAGE

Wire strands interfering with wire binding screws can cause false torque indication. Do not allow wire strands to interfere with threads of wire binding screws.

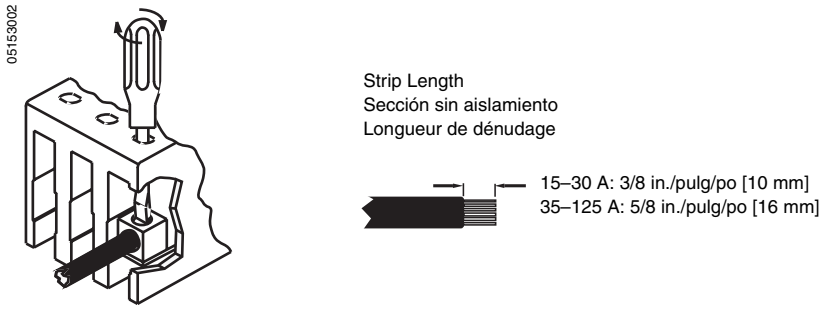
Failure to follow these instructions can result in equipment damage.

PELIGRO DE DAÑO AL EQUIPO

Los hilos del cable que interfieren con los tornillos de sujeción de cables pueden dar una indicación falsa de par de apriete. No permita que los hilos del cable interfieran con las roscas de los tornillos de sujeción de cables.

El incumplimiento de estas precauciones puede causar daño al equipo.

RISQUE DE DOMMAGES MATÉRIELS



Les torons du conducteur interférant avec les vis de fixation de fils peuvent entraîner une indication erronée du couple. Ne laissez pas les torons du conducteur s'engager dans les filets des vis de fixation de fils.

Si ces précautions ne sont pas respectées, cela peut entraîner des dommages matériels.

See circuit breaker faceplate label or optional lug instructions for wire size and torque.

Consulte la etiqueta de la placa frontal del interruptor automático o las instrucciones que acompañan a las zapatas opcionales para obtener el calibre del cable y el par de apriete.

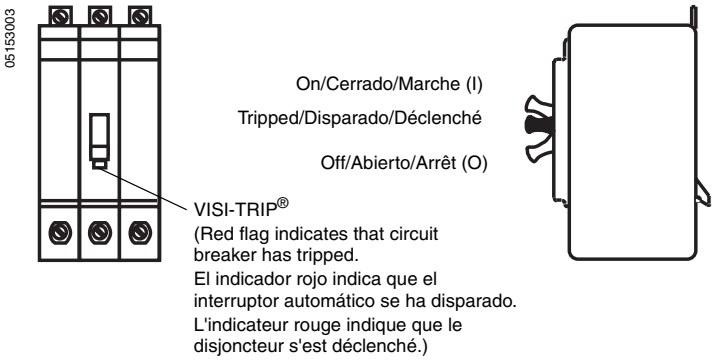
Voir l'étiquette de la plaque avant du disjoncteur ou les directives fournies avec les cosses optionnelles pour obtenir le calibre de fils et le couple.

CIRCUIT BREAKER REMOVAL

Remove circuit breaker in reverse order of installation.

DESMONTAJE DEL INTERRUPTOR AUTOMÁTICO

Desmonte el interruptor automático en el orden inverso al de la instalación.



DÉMONTAGE DU DISJONCTEUR

Démonter le disjoncteur en ordre inverse de l'installation.

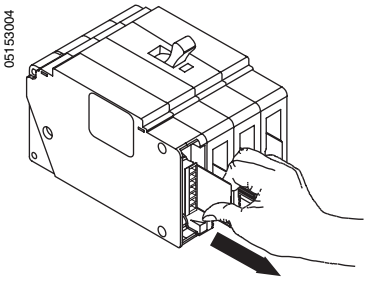
- Auxiliary switch/alarm switch package
- Shunt trip package
- Auxiliary switch/alarm switch/shunt trip package

1. Turn off all power supplying this equipment before working on or inside equipment. Turn off circuit breaker.
2. Use pull tab to remove connector from accessory receptacle.

ACCESORIOS ELÉCTRICOS

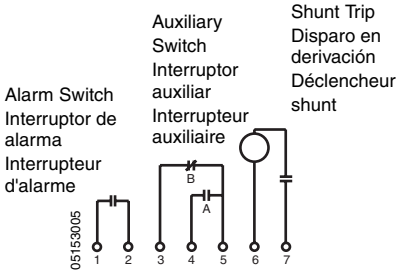
Opciones:

- Paquete de interruptor auxiliar e interruptor de alarma
- Paquete de disparo en derivación
- Paquete de interruptor auxiliar, interruptor de alarma y disparo en derivación



1. Desenergice el equipo antes de realizar cualquier trabajo en él. Descontar interuptor automático.
2. Utilice la lengüeta de extracción para retirar el conector del receptáculo del accesorio.

ACCESSOIRES ÉLECTRIQUES



Options :

- Ensemble d'interrupteur auxiliaire/interrupteur d'alarme
- Ensemble de déclencheur shunt
- Ensemble d'interrupteur auxiliaire/interrupteur d'alarme/déclencheur shunt

1. Couper l'alimentation de l'appareil avant d'y travailler. Couper l'alimentation à disjoncteur.
2. Tirer sur la languette pour retirer le connecteur du réceptacle de l'accessoire.

HAZARD OF ELECTRIC SHOCK, EXPLOSION, OR ARC FLASH

- Apply appropriate personal protective equipment (PPE) and follow safe electrical work practices. See NFPA 70E.
- This equipment must only be installed and serviced by qualified electrical personnel.
- Troubleshooting may require energizing auxiliary devices with test power supply. Make sure that the power supply is OFF before connecting or disconnecting it to auxiliary device.
- Do not touch the terminals of the device during the test.

Failure to follow these instructions will result in death or serious injury.

PELIGRO DE DESCARGA ELÉCTRICA, EXPLOSIÓN O DESTELLO POR ARQUEO

- Utilice equipo de protección personal (EPP) apropiado y siga las prácticas de seguridad eléctrica establecidas por su Compañía (consulte la norma NFPA 70E).
- Solamente el personal eléctrico especializado deberá instalar y prestar servicio de mantenimiento a este equipo.
- Para realizar un diagnóstico de problemas es necesario energizar los dispositivos auxiliares con la fuente de alimentación de prueba. Asegúrese que la fuente de alimentación esté DESCONECTADA antes de conectar o desconectar el dispositivo auxiliar.
- No toque las terminales del dispositivo durante la prueba.

El incumplimiento de estas instrucciones podrá causar la muerte o lesiones serias.

- Turn off all power supplying this equipment before working on or inside equipment.
- Always use a properly rated voltage sensing device to confirm power is off.
- Replace all devices, doors and covers before turning on power to this equipment.

Failure to follow these instructions will result in death or serious injury.

PELIGRO DE DESCARGA ELÉCTRICA, EXPLOSIÓN O DESTELLO POR ARQUEO

- Utilice equipo de protección personal (EPP) apropiado y siga las prácticas de seguridad en trabajos eléctricos establecidas por su Compañía, consulte la norma 70E de NFPA/Z462 de CSA y NOM-029-STPS.
- Solamente el personal eléctrico especializado deberá instalar y prestar servicio de mantenimiento a este equipo.
- Desenergice el equipo antes de realizar cualquier trabajo en él.
- Siempre utilice un dispositivo detector de tensión nominal adecuado para confirmar la desenergización del equipo.
- Vuelva a colocar todos los dispositivos, las puertas y las cubiertas antes de volver a energizar el equipo.

El incumplimiento de estas instrucciones podrá causar la muerte o lesiones serias.

RISQUE D'ÉLECTROCUTION, D'EXPLOSION OU D'ÉCLAIR D'ARC

- Portez un équipement de protection personnelle (ÉPP) approprié et observez les méthodes de travail électrique sécuritaire. Voir NFPA 70E ou CSA Z462.

- Coupez l'alimentation de l'appareil avant d'y travailler.
- Utilisez toujours un dispositif de détection de tension à valeur nominale appropriée pour s'assurer que l'alimentation est coupée.
- Replacez tous les dispositifs, les portes et les couvercles avant de mettre l'appareil sous tension.

Si ces directives ne sont pas respectées, cela entraînera la mort ou des blessures graves.

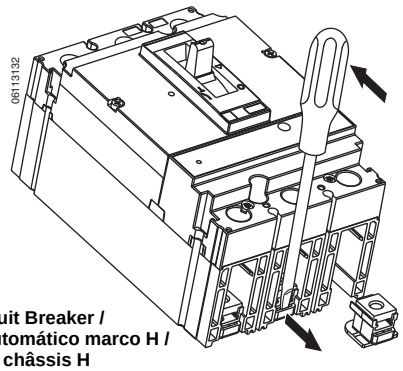
1. Turn off all power supplying this equipment before working on or inside equipment.
2. Verify circuit breaker is in off or tripped position.
3. Remove circuit breaker from enclosure, if installed.

1. Desenergice el equipo antes de realizar cualquier trabajo en él.
2. Asegúrese de que el interruptor esté en la posición de disparado o abierto (O).
3. Retire el interruptor automático del gabinete, si está instalado.

1. Couper l'alimentation de l'appareil avant d'y travailler.
2. S'assurer que le disjoncteur est en position d'arrêt (O) ou de déclenché.
3. Enlever le disjoncteur du coffret, s'il est installé.

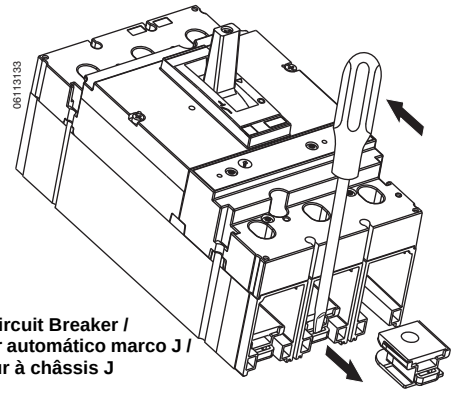
Lug Installation

1. If installed, remove existing terminal plate assembly from circuit breaker using slotted screwdriver.



Instalación del ensamble de zapatas

1. Si está instalada, retire el ensamble de placa terminal existente del interruptor utilizando un destornillador de punta plana.



Installation de l'assemblage de cosses

1. S'il a été installé, retirer l'assemblage de plaque de bornes existant du disjoncteur à l'aide d'un tournevis plat.

NOTICE / AVISO / AVIS

HAZARD OF FALSE TORQUE INDICATION

Do not allow conductor strands to interfere with threads of wire binding screw.

HAZARD OF OVERHEATING OR WIRE DISCONNECTION DURING SHORT CIRCUIT

Existing lug information may include incorrect wire torque for this lug. Install lug information label supplied with this kit over existing lug information.

Failure to follow these instructions can result in equipment damage.

PELIGRO DE INDICACIÓN FALSA DE PAR DE APRIETE

No permita que los hilos del conductor interfieran con las roscas del tornillo de sujeción del cable.

PELIGRO DE SOBRECALENTAMIENTO O DESCONEXIÓN DEL CABLE DURANTE UN CORTOCIRCUITO

La información de la zapata existente puede incluir un valor incorrecto de par de apriete del cable para esta zapata. Instale la etiqueta de datos de la zapata incluida con este kit sobre la etiqueta existente.

El incumplimiento de estas instrucciones puede causar daño al equipo.

RISQUE D'INDICATION ERRONÉE DU COUPLE

Ne laissez pas les torons du conducteur s'engager dans les filets de la vis de fixation.

RISQUE DE SURCHAUFFE OU DE DÉCONNEXION DE FILS DURANT UN COURT-CIRCUIT

Les informations existantes sur les cosses peuvent comprendre un couple de fil incorrect pour cette cosse. Installez l'étiquette de données sur les cosses fournies avec ce kit par-dessus celle existante.

Si ces directives ne sont pas respectées, cela peut entraîner des dommages matériels.

1. Square conductor ends and preform conductors to final configuration. Using a proper insulation stripping tool, strip conductor ends as recommended in Table 1. Do not nick strands.
2. Install cables and tighten wire-binding screw as recommended in Table 1.
   - — Wire larger than 12 AWG may be installed in center of channel.
   - — Install smaller wire (14–12 AWG) on the side of channel (A) on all lugs as shown in Figure 1, to avoid damage to wire.
3. Install appropriate new lug data label (B), included in lug kit, over existing lug data on circuit breaker.

1. Corte las puntas de los conductores en forma cuadrada y prefórmelos en la configuración final. Con una herramienta de desforramiento adecuada, pele las puntas de los conductores según la recomendación de la tabla 1. Tenga cuidado de no dañar los hilos.
2. Instale los cables y apriete los tornillos de sujeción según las recomendaciones de la tabla 1.
   - — Es posible instalar un conductor más grande que 3,31 mm^2 (12 AWG) en el centro del canal.
   - — Instale el conductor más pequeño de 2,08 a 3,31 mm^2 (14 a 12 AWG) en el costado del canal (A) en todas las zapatas para no dañar el conductor (vea la figura 1).
3. Instale la nueva etiqueta de datos de las zapatas (B), incluida con el kit de zapata, sobre la etiqueta existente en el interruptor automático.

1. Couper les extrémités des conducteurs bien droit et leur donner leur configuration définitive. Au moyen d'un outil à dénuder l'isolation approprié, dénuder les extrémités des conducteurs comme recommandé au tableau 1. Ne pas entailler les torons.
2. Installer les câbles et serrer les vis de fixation des fils comme recommandé au tableau 1.
   - — Du fil d'un calibre plus gros que 3,31 mm^2 (12 AWG) peut être installé au centre du profilé.
   - — Installer le fil plus petit (calibre 2,08 à 3,31 mm^2 [14 à 12 AWG]) sur le côté du profilé (A), sur toutes les cosses pour éviter d'endommager les fils (voir la figure 1).
3. Installer la nouvelle étiquette de données des cosses (B), comprise avec le kit, sur les données de cosses existantes du disjoncteur.

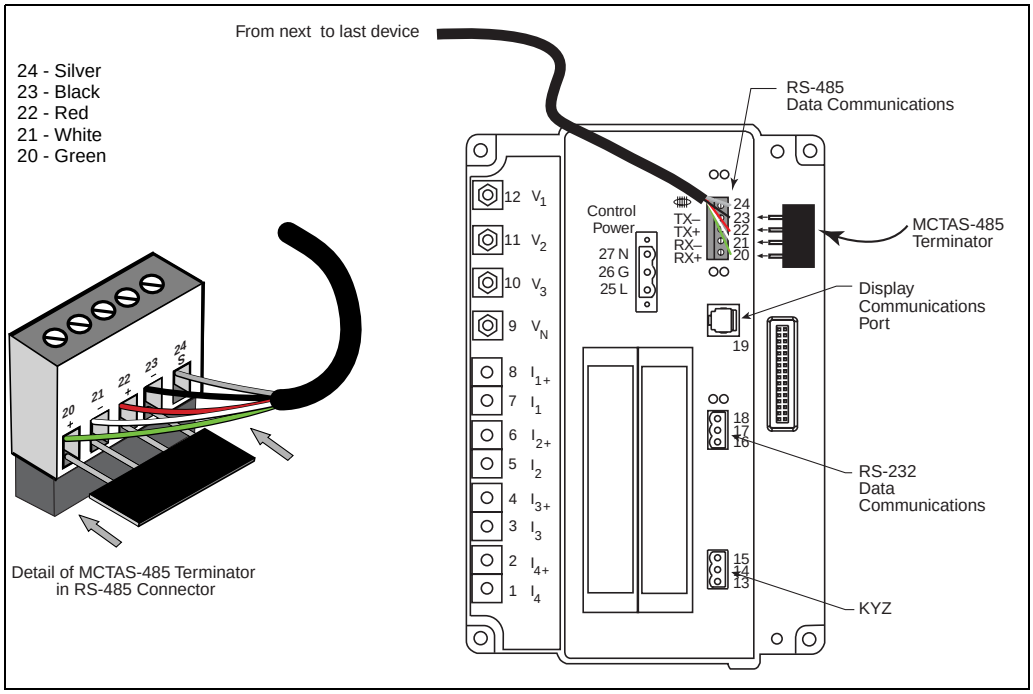
Terminating the Communications Link

For proper RS-485 communications performance, you must terminate the last device on the communications link using one of these methods:



- Use the MCTAS-485 terminator, which inserts directly into the connector in the RS-485 port of the circuit monitor/power meter as illustrated in Figure 6–7.
- Use a terminal block and the MCT-485 terminator. In this method, communications wires route from the last device on a daisy chain to a 5-position terminal block. The terminator attaches to the terminal block. See Figure 6–8.

- Terminate **only the last device** on the link. If a link has only one device, terminate that device.
- Some PowerLogic devices use a removable communications connector. If the last device on the communications link is not a circuit monitor/power meter, refer to the instruction bulletin for that device for termination instructions.

Using the MCTAS-485 Terminator

To terminate the circuit monitor/power meter using the MCTAS-485 terminator, insert the wires of the terminator directly into terminals 20, 21, 22, and 23 of the RS-485 communications connector on the circuit monitor/power meter as shown in Figure 6–7.

Figure 6–7: Terminating the circuit monitor/power meter using the MCTAS-485 terminator

Using the MCT-485 Terminator

If the circuit monitor/power meter is the last device on the communication link, follow these instructions to terminate it using the MCT-485 terminator:

1. Route the communications wires from the last circuit monitor/power meter on a daisy chain to a 5-position terminal block.
2. Attach the terminator to the terminal block as shown in Figure 6–8.

Register today in **one easy step** to receive valuable benefits!

Start taking advantage of the benefits now!

> **Save** on Spare Parts

Minimize downtime and save money by having spare parts available when you need them.
Schneider Electric Field Services will evaluate your electric system, identify the equipment that is critical to your operations, recommend specific spare parts, and offer shipping management solutions.

> **Protect** your new equipment investment and receive an extended warranty[1]

Improper installation is a leading cause of equipment failure.
Our start-up and commissioning services confirm that your equipment is installed properly, meets factory standards, and passes our stringent performance tests to help minimize downtime and delays in the future.

> **Sign-up** for a 36-month Advantage Service Plan and receive 12 additional months FREE![1]

Mitigate your risk of downtime and unexpected repair costs.
Without a proper maintenance strategy for your electrical distribution equipment, it's just a matter of time before costly breakdowns will occur. Having an Advantage Service Plan in place minimizes unplanned outages and remedial actions. Should an issue arise, we will ensure prompt response to get you back up and running. Best of all, our fixed-cost service plans take the guess-work out of your budget since there are no hidden charges.

> **Receive** Discounts on Training Courses

Over 70 training courses are available regionally, on-site, or online to meet your needs.
Schneider Electric instructors are experienced engineers and technicians who utilize their real-world experience in the classroom. As the equipment manufacturer, we provide expertise and accurate, up-to-date materials.

[1] Only applicable if Schneider Electric Field Services provide start-up and commissioning services.

⚠ WARNING

This product contains and/or emits chemicals known to the State of California to cause cancer, birth defects, or other reproductive harm.

California Proposition 65

⚠ WARNING

Breathing diesel engine exhaust exposes you to chemicals known to the State of California to cause cancer and birth defects or other reproductive harm.

- Always start and operate the engine in a well-ventilated area.
- If in an enclosed area, vent the exhaust to the outside.
- Do not modify or tamper with exhaust system.
- Do not idle the engine except as necessary.

IMPORTANT SAFETY INSTRUCTIONS. Electromechanical equipment, including generator sets, transfer switches, switchgear, and accessories, can cause bodily harm and pose life-threatening danger when improperly installed, operated, or maintained. To prevent accidents be aware of potential dangers and act safely. Read and follow all safety precautions and instructions. SAVE THESE INSTRUCTIONS.

This manual has several types of safety precautions and instructions: Danger, Warning, Caution, and Notice.

DANGER

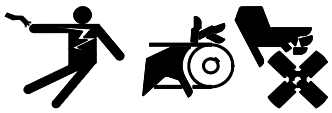
Danger indicates the presence of a hazard that ***will cause severe personal injury, death***, or ***substantial property damage***.

WARNING

Warning indicates the presence of a hazard that ***can cause severe personal injury, death,*** or ***substantial property damage***.

CAUTION

Caution indicates the presence of a hazard that ***will*** or ***can cause minor personal injury*** or ***property damage***.



NOTICE

Notice communicates installation, operation, or maintenance information that is safety related but not hazard related.

Safety decals affixed to the equipment in prominent places alert the operator or service technician to potential hazards and explain how to act safely. The decals are shown throughout this publication to improve operator recognition. Replace missing or damaged decals.

Accidental Starting

WARNING

Accidental starting.
Can cause severe injury or death.

Disconnect the battery cables before working on the generator set. Remove the negative (-) lead first when disconnecting the battery. Reconnect the negative (-) lead last when reconnecting the battery.

Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) Move the generator set master switch to the OFF position. (2) Disconnect the power to the battery charger. (3) Remove the battery cables, negative (-) lead first. Reconnect the negative (-) lead last when reconnecting the battery. Follow these precautions to prevent starting of the generator set by an automatic transfer switch, remote start/stop switch, or engine start command from a remote computer.

(Decision-Maker® 3+ and 550 Controllers)

Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) Press the generator set off/reset button to shut down the generator set. (2) Disconnect the power to the battery charger, if equipped. (3) Remove the battery cables, negative (-) lead first. Reconnect the negative (-) lead last when reconnecting the battery. Follow these precautions to prevent the starting of the generator set by the remote start/stop switch.

(Decision-Maker® 3000, 3500, and 6000 Controllers)

Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) If the controller is not already in the MAN (manual) mode, press the Controller Mode button and then press the MAN mode button. (2) If the generator set is running, press and hold the Manual–Stop button for at least 2 seconds to stop the generator set. (3) Press the Controller Mode button and then press the controller Off mode button. (4) Disconnect the power to the battery charger, if equipped. (5) Remove the battery cables, negative (-) lead first. Reconnect the negative (-) lead last when reconnecting the battery. Follow these precautions to prevent the starting of the generator set by the remote start/stop switch.

(Decision-Maker® 8000 Controller)

Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) Shut down the generator set. (2) Place the controller in Out of Service mode. (3) Press the emergency stop button. (4) Disconnect the power to the battery charger, if equipped. (5) Remove the battery cables, negative (-) lead first. Reconnect the negative (-) lead last when reconnecting the battery. Follow these precautions to prevent the starting of the generator set by the remote start/stop switch.

Battery

⚠ WARNING

Sulfuric acid in batteries.
Can cause severe injury or death.

Wear protective goggles and clothing. Battery acid may cause blindness and burn skin.

⚠ WARNING

Explosion.
Can cause severe injury or death.
Relays in the battery charger cause arcs or sparks.

Locate the battery in a well-ventilated area. Isolate the battery charger from explosive fumes.

Battery electrolyte is a diluted sulfuric acid. Battery acid can cause severe injury or death. Battery acid can cause blindness and burn skin. Always wear splashproof safety goggles, rubber gloves, and boots when servicing the battery. Do not open a sealed battery or mutilate the battery case. If battery acid splashes in the eyes or on the skin, immediately flush the affected area for 15 minutes with large quantities of clean water. Seek immediate medical aid in the case of eye contact. Never add acid to a battery after placing the battery in service, as this may result in hazardous spattering of battery acid.

Battery acid cleanup. Battery acid can cause severe injury or death. Battery acid is electrically conductive and corrosive. Add 500 g (1 lb.) of bicarbonate of soda (baking soda) to a container with 4 L (1 gal.) of water and mix the neutralizing solution. Pour the neutralizing solution on the spilled battery acid and continue to add the neutralizing solution to the spilled battery acid until all evidence of a chemical reaction (foaming) has ceased. Flush the resulting liquid with water and dry the area.

Battery gases. Explosion can cause severe injury or death. Battery gases can cause an explosion. Do not smoke or permit flames or sparks to occur near a battery at any time, particularly when it is charging. Do not dispose of a battery in a fire. To prevent burns and sparks that could cause an explosion, avoid touching the battery terminals with tools or other metal objects. Remove all jewelry before servicing the equipment. Discharge static electricity from your body before touching batteries by first touching a grounded metal surface away from the battery. To avoid sparks, do not disturb the battery charger connections while the battery is charging. Always turn the battery charger off before disconnecting the battery connections. Ventilate the compartments containing batteries to prevent accumulation of explosive gases.

Battery short circuits. Explosion can cause severe injury or death. Short circuits can cause bodily injury and/or equipment damage. Disconnect the battery before generator set installation or maintenance. Remove all jewelry before servicing the equipment. Use tools with insulated handles. Remove the negative (–) lead first when disconnecting the battery. Reconnect the negative (–) lead last when reconnecting the battery. Never connect the negative (–) battery cable to the positive (+) connection terminal of the starter solenoid. Do not test the battery condition by shorting the terminals together.

Engine Backfire/Flash Fire

⚠ WARNING

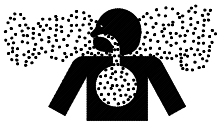
Risk of fire.
Can cause severe injury or death.

Do not smoke or permit flames or sparks near fuels or the fuel system.

Servicing the fuel system. A flash fire can cause severe injury or death. Do not smoke or permit flames or sparks near the fuel mixer, fuel line, fuel filter, or other potential sources of fuel vapors. When removing the fuel line or fuel system be aware that liquid propane can cause frostbite on contact.

(Gas-fueled Model)

Servicing the fuel system. A flash fire can cause severe injury or death. Do not smoke or permit flames or sparks near the fuel injection system, fuel line, fuel filter, fuel pump, or other potential sources of spilled fuels or fuel vapors. Catch fuels in an approved container when removing the fuel line or fuel system.



(Diesel-fueled Model)

Servicing the air cleaner. A sudden backfire can cause severe injury or death. Do not operate the generator set with the air cleaner removed.

Combustible materials. A fire can cause severe injury or death. Generator set engine fuels and fuel vapors are flammable and explosive. Handle these materials carefully to minimize the risk of fire or explosion. Equip the compartment or nearby area with a fully charged fire extinguisher. Select a fire extinguisher rated ABC or BC for electrical fires or as recommended by the local fire code or an authorized agency. Train all personnel on fire extinguisher operation and fire prevention procedures.

Exhaust System

⚠ WARNING

Carbon monoxide.
Can cause severe nausea, fainting, or death.

The exhaust system must be leakproof and routinely inspected.

Generator set operation. Carbon monoxide can cause severe nausea, fainting, or death. Carbon monoxide is an odorless, colorless, tasteless, nonirritating gas that can cause death if inhaled for even a short time. Avoid breathing exhaust fumes when working on or near the generator set. Never operate the generator set inside a building unless the exhaust gas is piped safely outside. Never operate the generator set where exhaust gas could accumulate and seep back inside a potentially occupied building.

Carbon monoxide symptoms. Carbon monoxide can cause severe nausea, fainting, or death. Carbon monoxide is a poisonous gas present in exhaust gases. Carbon monoxide is an odorless, colorless, tasteless, nonirritating gas that can cause death if inhaled for even a short time. Carbon monoxide poisoning symptoms include but are not limited to the following:

- Light-headedness, dizziness
- Physical fatigue, weakness in joints and muscles
- Sleepiness, mental fatigue, inability to concentrate or speak clearly, blurred vision
- Stomachache, vomiting, nausea

If experiencing any of these symptoms and carbon monoxide poisoning is possible, seek fresh air immediately and remain active. Do not sit, lie down, or fall asleep. Alert others to the possibility of carbon monoxide poisoning. Seek medical attention if the condition of affected persons does not improve within minutes of breathing fresh air.

Fuel System

⚠ WARNING

Explosive fuel vapors.
Can cause severe injury or death.

Use extreme care when handling, storing, and using fuels.

⚠ WARNING

Avoid high pressure fluids.
Can cause severe injury or death.

Do not work on high pressure fuel or hydraulic systems without protective equipment to protect hands, eyes, and body. Avoid the hazard by relieving pressure before disconnecting fuel injection pressure lines. Search for leaks using a piece of cardboard. Always protect hands, eyes, and body from high pressure fluids. If an accident occurs, seek medical attention immediately.

The fuel system. Explosive fuel vapors can cause severe injury or death. Vaporized fuels are highly explosive. Use extreme care when handling and storing fuels. Store fuels in a well-ventilated area away from spark-producing equipment and out of the reach of children. Never add fuel to the tank while the engine is running because spilled fuel may ignite on contact with hot parts or from sparks. Do not smoke or permit flames or sparks to occur near sources of spilled fuel or fuel vapors. Keep the fuel lines and connections tight and in good condition. Do not replace flexible fuel lines with rigid lines. Use flexible sections to avoid fuel line breakage caused by vibration. Do not operate the generator set in the presence of fuel leaks, fuel accumulation, or sparks. Repair fuel systems before resuming generator set operation.

Explosive fuel vapors can cause severe injury or death. Take additional precautions when using the following fuels:

Gasoline—Store gasoline only in approved red containers clearly marked GASOLINE.

Propane (LPG)—Adequate ventilation is mandatory. Because propane is heavier than air, install propane gas detectors low in a room. Inspect the detectors per the manufacturer's instructions.

Natural Gas—Adequate ventilation is mandatory. Because natural gas rises, install natural gas detectors high in a room. Inspect the detectors per the manufacturer's instructions.

Fuel tanks. Explosive fuel vapors can cause severe injury or death. Gasoline and other volatile fuels stored in day tanks or subbase fuel tanks can cause an explosion. Store only diesel fuel in tanks.

Draining the fuel system. Explosive fuel vapors can cause severe injury or death. Spilled fuel can cause an explosion. Use a container to catch fuel when draining the fuel system. Wipe up spilled fuel after draining the system.

Gas fuel leaks. Explosive fuel vapors can cause severe injury or death. Fuel leakage can cause an explosion. Check the LPG vapor or natural gas fuel system for leakage by using a soap and water solution with the fuel system test pressurized to 6–8 ounces per square inch (10–14 inches water column). Do not use a soap solution containing either ammonia or chlorine because both prevent bubble formation. A successful test depends on the ability of the solution to bubble.

LPG liquid withdrawal fuel leaks. Explosive fuel vapors can cause severe injury or death. Fuel leakage can cause an explosion. Check the LPG liquid withdrawal fuel system for leakage by using a soap and water solution with the fuel system test pressurized to at least 90 psi (621 kPa). Do not use a soap solution containing either ammonia or chlorine because both prevent bubble formation. A successful test depends on the ability of the solution to bubble.

Hazardous Noise

⚠ CAUTION

Hazardous noise.
Can cause hearing loss.

Never operate the generator set without a muffler or with a faulty exhaust system.

Engine noise. Hazardous noise can cause hearing loss. Generator sets not equipped with sound enclosures can produce noise levels greater than 105 dBA. Prolonged exposure to noise levels greater than 85 dBA can cause permanent hearing loss. Wear hearing protection when near an operating generator set.

Hazardous Voltage/ Moving Parts

⚠ DANGER

Hazardous voltage.
Will cause severe injury or death.

Disconnect all power sources before opening the enclosure.

⚠ WARNING

Hazardous voltage. Moving parts.
Can cause severe injury or death.

Operate the generator set only when all guards and electrical enclosures are in place.

⚠ WARNING

Hazardous voltage.
Backfeed to the utility system can cause property damage, severe injury, or death.

If the generator set is used for standby power, install an automatic transfer switch to prevent inadvertent interconnection of standby and normal sources of supply.

⚠ CAUTION

Welding the generator set.
Can cause severe electrical equipment damage.

Never weld components of the generator set without first disconnecting the battery, controller wiring harness, and engine electronic control module (ECM).

Servicing the generator set when it is operating. Exposed moving parts can cause severe injury or death. Keep hands, feet, hair, clothing, and test leads away from the belts and pulleys when the generator set is running. Replace guards, screens, and covers before operating the generator set.

Grounding electrical equipment. Hazardous voltage can cause severe injury or death. Electrocution is possible whenever electricity is present. Ensure you comply with all applicable codes and standards. Electrically ground the generator set, transfer switch, and related equipment and electrical circuits. Turn off the main circuit breakers of all power sources before servicing the equipment. Never contact electrical leads or appliances when standing in water or on wet ground because these conditions increase the risk of electrocution.

Welding on the generator set. Can cause severe electrical equipment damage. Before welding on the generator set perform the following steps: (1) Remove the battery cables, negative (–) lead first. (2) Disconnect all engine electronic control module (ECM) connectors. (3) Disconnect all generator set controller and voltage regulator circuit board connectors. (4) Disconnect the engine battery-charging alternator connections. (5) Attach the weld ground connection close to the weld location.

Installing the battery charger. Hazardous voltage can cause severe injury or death. An ungrounded battery charger may cause electrical shock. Connect the battery charger enclosure to the ground of a permanent wiring system. As an alternative, install an equipment grounding conductor with circuit conductors and connect it to the equipment grounding terminal or the lead on the battery charger. Install the battery charger as prescribed in the equipment manual. Install the battery charger in compliance with local codes and ordinances.

Connecting the battery and the battery charger. Hazardous voltage can cause severe injury or death. Reconnect the battery correctly, positive to positive and negative to negative, to avoid electrical shock and damage to the battery charger and battery(ies). Have a qualified electrician install the battery(ies).

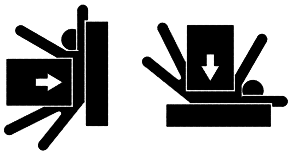
Short circuits. Hazardous voltage/current can cause severe injury or death. Short circuits can cause bodily injury and/or equipment damage**.** Do not contact electrical connections with tools or jewelry while making adjustments or repairs. Remove all jewelry before servicing the equipment.

Engine block heater. Hazardous voltage can cause severe injury or death. The engine block heater can cause electrical shock. Remove the engine block heater plug from the electrical outlet before working on the block heater electrical connections.

Electrical backfeed to the utility. Hazardous backfeed voltage can cause severe injury or death. Install a transfer switch in standby power installations to prevent the connection of standby and other sources of power. Electrical backfeed into a utility electrical system can cause severe injury or death to utility personnel working on power lines.

Testing live electrical circuits. Hazardous voltage or current can cause severe injury or death. Have trained and qualified personnel take diagnostic measurements of live circuits. Use adequately rated test equipment with electrically insulated probes and follow the instructions of the test equipment manufacturer when performing voltage tests. Observe the following precautions when performing voltage tests: (1) Remove all jewelry. (2) Stand on a dry, approved electrically insulated mat. (3) Do not touch the enclosure or components inside the enclosure. (4) Be prepared for the system to operate automatically.
(600 volts and under)

Heavy Equipment



⚠ WARNING

Unbalanced weight.
Improper lifting can cause severe injury or death and equipment damage.

Do not use lifting eyes.
Lift the generator set using lifting bars inserted through the lifting holes on the skid.

⚠ WARNING

Unbalanced and elevated weight.
Improper lifting can cause severe injury or death and equipment damage.

Do not lift the generator set from the engine or alternator eyes. Never stand under a unit being lifted. Always maintain a safe distance from the unit being lifted.
See the lifting instructions in the installation manual that was provided with the unit.

Hot Parts

⚠ WARNING

Hot coolant and steam.
Can cause severe injury or death.

Before removing the pressure cap, stop the generator set and allow it to cool. Then loosen the pressure cap to relieve pressure.

⚠ WARNING

Hot engine and exhaust system.
Can cause severe injury or death.

Do not work on the generator set until it cools.

Servicing the exhaust system. Hot parts can cause severe injury or death. Do not touch hot engine parts. The engine and exhaust system components become extremely hot during operation.

Servicing the engine heater. Hot parts can cause minor personal injury or property damage. Install the heater before connecting it to power. Operating the heater before installation can cause burns and component damage. Disconnect power to the heater and allow it to cool before servicing the heater or nearby parts.

Notice

NOTICE

This generator set has been rewired from its nameplate voltage to

246242

NOTICE

Voltage reconnection. Affix a notice to the generator set after reconnecting the set to a voltage different from the voltage on the nameplate. Order voltage reconnection decal 246242 from an authorized service distributor/dealer.

NOTICE

Parallel Operation. This product includes features intended to support operation in parallel with the utility grid, but these features have not been evaluated for compliance with specific utility interconnection protection standards or requirements.

NOTICE

Canadian installations only. For standby service connect the output of the generator set to a suitably rated transfer switch in accordance with Canadian Electrical Code, Part 1.

NOTICE

Electrostatic discharge damage. Electrostatic discharge (ESD) damages electronic circuit boards. Prevent electrostatic discharge damage by wearing an approved grounding wrist strap when handling electronic circuit boards or integrated circuits. An approved grounding wrist strap provides a high resistance (about 1 megohm), *not a direct short*, to ground.

Notes

This manual provides installation instructions for industrial generator sets. Operation manuals and wiring diagram manuals are available separately.

Some additional model-specific installation information may be included in the respective generator set controller operation manual.

Information in this publication represents data available at the time of print. Kohler Co. reserves the right to change this publication and the products represented without notice and without any obligation or liability whatsoever.

Read this manual and carefully follow all procedures and safety precautions to ensure proper equipment operation and to avoid bodily injury. Read and follow the Safety Precautions and Instructions section at the beginning of this manual. Keep this manual with the equipment for future reference.

Abbreviations

This publication makes use of numerous abbreviations. Typically, the word(s) are spelled out along with the abbreviation in parentheses when shown for the first time in a section. Appendix A, Abbreviations, also includes many abbreviation definitions.

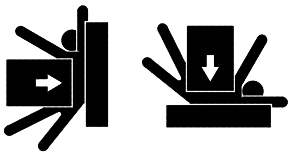
This manual references several organizations and their codes that provide installation requirements and guidelines such as the National Fire Protection Association (NFPA) and Underwriter's Laboratories Inc. (UL).

- NFPA 54 National Fuel Gas Code
- NFPA 70 National Electrical Code®; the National Electrical Code is a registered trademark of the NFPA
- NFPA 99 Standard for Health Care Facilities
- NFPA 101 Life Safety Code
- NFPA 110 Emergency and Standby Power Systems
- UL 486A–486B Wire Connectors
- UL 486E Equipment Wiring Terminals for Use with Aluminum and/or Copper Conductors
- UL 2200 Stationary Engine Generator Assemblies

These organizations provide information specifically for US installations. Installers must comply with all applicable national and local codes.

Before beginning generator set installation, record the following data from the generator set's specification sheet and keep this data accessible for reference during installation:



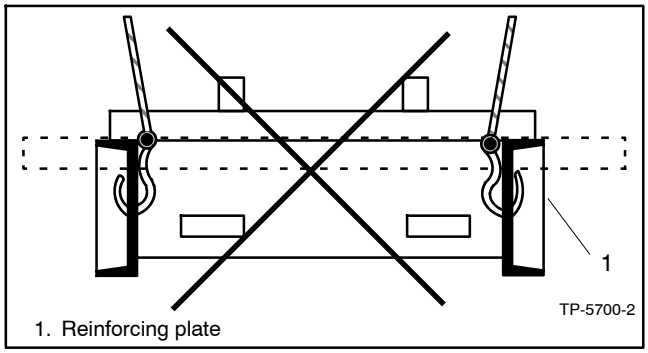
- Dimensions and weight (verify dimensions and weight using the submittal data)
- Exhaust outlet size and maximum allowable backpressure
- Battery CCA rating and quantity
- Fuel supply line size and fuel pressure requirement (gas models)
- Air requirements

The loading and transporting processes expose the generator set to many stresses and the possibility of improper handling. Therefore, after transporting industrial generator sets:

- Check the alignment of the radiator and supports to ensure that the radiator is evenly spaced from the generator and that supports are square and of even length. Check the radiator fan for uniform alignment and equal clearance within the radiator shroud. Adjust if necessary.
- After confirming the correct alignment, tighten the hardware to its specified torque. Reference Appendix C, General Torque Specifications.

2.1 Lifting

⚠ WARNING



Unbalanced and elevated weight. Improper lifting can cause severe injury or death and equipment damage.

Do not lift the generator set from the engine or alternator eyes. Never stand under a unit being lifted. Always maintain a safe distance from the unit being lifted.
See the lifting instructions in the installation manual that was provided with the unit.

2.1.1 General Precautions

Follow these general precautions when lifting all generator sets and related equipment.

- Install proper size rigging at the skid lifting eyes providing a direct pull on the skid lifting eye. Make sure the rigging does not work as a pry bar lever against the lifting eye.
- Do not lift the generator set using the lifting eyes attached to the engine and/or alternator as these lifting eyes can not support the total weight of the generator set.
- Always protect cables, chains, and straps from sharp edges.

1. Reinforcing plate

Figure 2-1 Improper Lifting Hook Placement (above 1000 kW)

- Generator sets typically above 1000 kW may have reinforcing plates on the skid. Do not attach lifting hooks to the reinforcing plate. See Figure 2-1.
- Lifting should only be conducted by those trained and experienced in lifting and rigging to achieve a safe and effective lift. Consideration needs to be given to, but not necessarily limited to, the following items:
  - Weight and center of gravity of the equipment being lifted
  - Weight and center of gravity of the lifting device
  - Boom angles
  - Selection of rated rigging
  - Stability of lifting foundation
  - Wind and weather conditions
  - Local or regional codes that may require or restrict types of rigging.
- Use a spreader bar to prevent lifting cables from contacting air cleaners, shrouds, and other protruding components. If the cables still do not clear these components, remove the components.

2.1.2 Weight and Center of Gravity

Refer to the respective specification sheet and/or the submittal drawing for the weight and center of gravity of all components being lifted. The total combined weight and center of gravity must be known to select the proper rigging. If the weight and center of gravity is not readily available, contact your distributor/dealer.

As applicable, determine the weight and center of gravity of the following components:

- Generator set
- Enclosure system (includes silencer, inlet baffles, louvers, etc.)
- Subbase fuel tank (lift only empty fuel tanks).

2.1.3 Lifting the Generator Set

The distributor/lifting contractor should choose one of the following methods to lift the generator set depending upon the location circumstances and the generator set's weight and size. Remove cover plates as needed to access the generator set skid lifting eyes.

Single Spreader Bar and Hook Method

Refer to Figure 2-2.

Double Spreader Bar and Hook Method

Refer to Figure 2-3.

2.1.4 Lifting the Subbase Fuel Tank

This section deals with lifting the subbase fuel tank as a single unit.

- The subbase fuel tank *must* have lifting eyes in order to use the following methods.
- The subbase fuel tank must be empty. Do not lift a fuel tank containing fuel (or any liquid).
- Remove any vent piping longer than 1 m (3.3 ft.) from the fuel tank. Do not lift a fuel tank with attached vent piping longer than 1 m (3.3 ft.).
- Attach one or two spreader bars as shown.

Fuel Tank with Single Spreader Bar Method

Refer to Figure 2-7.

2.1.5 Lifting the Generator Set with Attached Enclosure

Enclosure Attached Directly to the Generator Set Skid

Refer to Figure 2-8. Lift the assembly by lifting on the skid as shown in 2.1.3 Lifting Methods for Generator Set.

Do not attach hoisting equipment to the enclosure.

2.1.6 Lifting the Generator Set, Enclosure, and Subbase Fuel Tank Assembly

When using the subbase fuel tank to lift the generator set and/or enclosure as a package, use ALL of the lifting eyes on the subbase fuel tank.

Hoisting using Four Eye Lifting Method

Apply the same lifting methods using single or double spreader bars as shown in 2.1.3 Lifting the Generator Set.

Hoisting using Six Eye Lifting Method

Apply one spreader bar and two chain falls (Figure 2-11) or three spreader bars and two chain falls (Figure 2-12) for six eye lifting.

- Install a pair of outer slings to the maximum angle as shown in Figure 2-11 and Figure 2-12.
- Remove the slack from the slings in the system but do not lift the unit.
- Install adjustable chain falls and strap or cable them from the spreader bar to the middle lifting eyes. Adjust to remove the slack.
- Check and remove any slack that has developed in the primary slings and check that all chains/straps/cables are carrying load.

Hoisting using Eight Eye Lifting Method

Apply two spreader bars and four chain falls (Figure 2-13) for eight eye lifting.

- Install a pair of outer slings up to the maximum angle as shown in Figure 2-13.
- Remove the slack from the slings in the system but do not lift the unit.
- Install adjustable chain falls and strap or cable them from the spreader bar to the middle lifting eyes. Adjust to remove the slack.
- Check and remove any slack that has developed in the primary slings and check that all chains/straps/cables are carrying load.

Hoisting using Ten Eye Lifting Method

Apply three spreader bars and six chain falls (Figure 2-14) for ten eye lifting.

- Install a pair of outer slings up to the maximum angle as shown in Figure 2-14.
- Remove the slack from the slings in the system but do not lift the unit.
- Install adjustable chain falls and strap or cable them from the spreader bar to the middle lifting eyes. Adjust to remove the slack.
- Check and remove any slack that has developed in the primary slings and check that all chains/straps/cables are carrying load.

Hoisting using Twelve Eye Lifting Method

Apply three spreader bars and eight chain falls (Figure 2-15) for twelve eye lifting.

- Install a pair of outer slings up to the maximum angle as shown in Figure 2-15.
- Remove the slack from the slings in the system but do not lift the unit.
- Install adjustable chain falls and strap or cable them from the spreader bar to the middle lifting eyes. Adjust to remove the slack.
- Check and remove any slack that has developed in the primary slings and check that all chains/straps/cables are carrying load.

2.1.7 Lifting Single Point Lift Assemblies

Some units have an enclosure integral to the skid and attach a single point lifting eye located at the top and center of the enclosure. The entire assembly may be lifted with this eye.

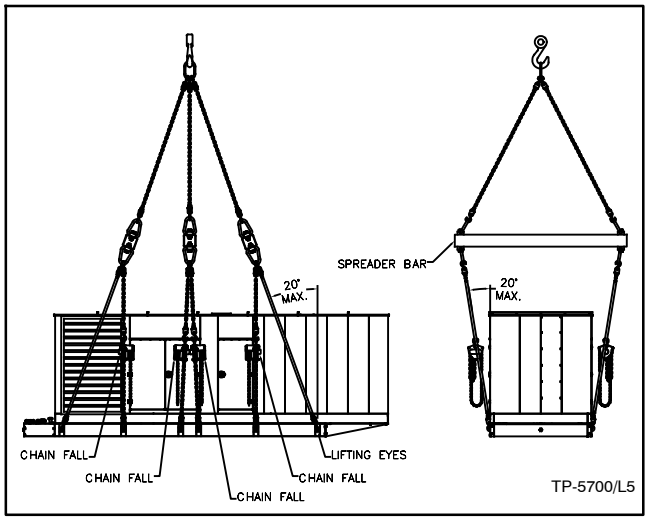

Figure 2-15 Twelve Eyes, Three Spreader Bars, and Eight Chain Falls Lifting Method

2.2 Generator Set Transporting

Follow these guidelines when transporting the generator set:

- Select the transporting vehicle/trailer based on the dimensions and weight of the generator set as specified in the generator set dimension drawing or specification sheet. Ensure that the gross weight and overall height of the generator set and vehicle/trailer in transport does not exceed applicable transportation codes.
- Use low boy-type trailers that meet clearance requirements when transporting units larger than 1000 kW. Load large (unboxed) radiator-equipped generator sets with the radiator facing the rear to reduce wind resistance during transit. Secure fans to prevent fan rotation in transit.
- Securely fasten the generator set to the vehicle/trailer. Even the heaviest of generator sets can move during shipment unless they are secured. Fasten the generator set to the vehicle/trailer bed with a correctly sized chain routed through the mounting holes of the generator set skid (or tank, if equipped). Use chain tighteners to remove slack from the mounting chain. Do not use strapping over the top of an enclosed generator set as damage to the enclosure may occur.
- Always cover a non-enclosed unit with a heavy-duty canvas or tarpaulin secured to the generator set or trailer.

3.1 Location Factors

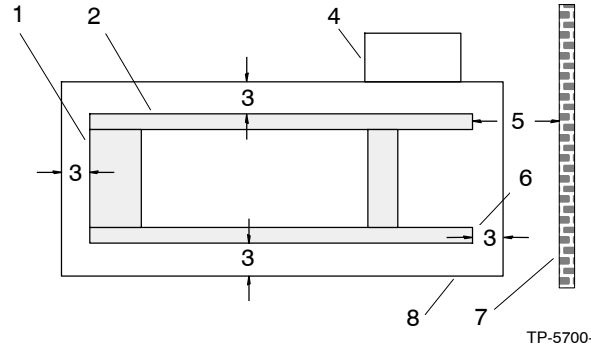
Ideally, the generator set should be mounted on concrete at ground level. For above-ground installations, including roof installations, weight considerations are especially important. The building engineer determines whether the structure can support the weight of the generator set.

The location of the generator set must meet the following criteria.

General:

- Mounting surface is square and horizontally level at all four edges.
- Support the weight of the generator set and related equipment such as fuel storage tanks, batteries, radiators, and mounting pad(s). Keep in mind that the mounting pad weight may exceed the weight of the generator set.
- Mounting pad should be designed to prevent the vibration of a running unit from causing mounting pad distortion and affecting engine/alternator alignment.
- Meet applicable fire rating codes and standards.
- Install the unit so that the risk of contact by people with the hot generator set surfaces is minimized.
- Position the generator set over a noncombustible surface. If the mounting surface directly under or near the generator set is porous or deteriorates from exposure to engine fluids, construct a containment pan for spilled fuel, oil, coolant, and battery electrolyte. Do not allow accumulation of combustible materials under the generator set.
- Permit vibration isolation and dampening to reduce noise and prevent damage.
- Be clean, dry, and not subject to flooding.
- Provide easy access for service and repair.

Indoor Installations:



- Allow adequate ventilation with a minimum amount of ductwork.
- Allow safe expulsion of exhaust.
- Allow for storage of sufficient fuel to sustain emergency operation. See the generator set specification sheet for fuel consumption.
- Allow for locating the fuel tank within the vertical lift capabilities of the fuel pump and any auxiliary pumps. See Section 6, Fuel Systems.
- Minimize the risk of public or unauthorized access.
- Provide adequate protection to prevent injury in the stub-up area. If the stub-up area opening is exposed, provide a cover or fill in the area to avoid the risk of tripping or falling into the stub-up opening.

Outdoor Installations:

- Select a location that provides adequate air flow. Avoid locations next to tall buildings that block normal air flow and cause air vacuum pockets. Avoid areas that are subject to high winds, excessive dust, or other airborne contaminants. High dust areas may require more frequent air cleaner maintenance. High temperature conditions affect generator set efficiency. Select a shaded area away from direct sunlight and/or other heat-producing equipment when practical.
- Avoid areas with combustible materials, including but not limited to building materials as well as natural surroundings. Keep dry field grass, foliage, and combustible landscaping materials a safe distance from the exhaust system.
- The subsoil location must have a bearing strength capable of supporting the generator set and mounting pad combined weight. Analysis by a qualified technician or engineer is recommended to determine the proper excavation material required.
- If the generator set enclosure is mounted on multiple pads where it is elevated above the main surface it may cause discharge air recirculation underneath the unit. A typical location could be a building roof where the main surface is uneven for a single pad. Refer to 4.3.2 Installation Considerations for information to minimize discharge air recirculation.
- Select a location that provides adequate space to access and service the unit. Allow for adequate clearance to open and close access doors. Avoid locations on a hill or steep embankment unless provision is made to include a servicing platform.

3.2 Mounting Surface

Figure 3-1 shows typical mounting surface details for sizing the concrete surface beyond the generator set and allowing for clearances during generator set service. Follow the dimensional details provided in Figure 3-2, Figure 3-3, or Figure 3-4 depending upon the mounting method.

1. Engine end
2. Generator set skid
3. Extend the concrete surface a minimum of 152 mm (6 in.) beyond the generator set
4. Battery rack
5. Allow at least 457 mm (18 in.) between the generator set and adjacent walls or other obstructions *on all sides* for ease of servicing the generator set
6. Alternator end
7. Building wall
8. Mounting pad (concrete surface)

Figure 3-1 Mounting Surface Detail (top view)

3.2.1 Single-Pad Mounting

The manufacturer recommends a single, level concrete mounting pad as shown in Figure 3-2. This method provides maximum stability for the generator set; however, draining the oil and servicing the generator set may require raising the set from the pad.

Use an oil drain pump if clearance below the oil drain or extension is insufficient for a pan large enough to hold all the engine's oil.

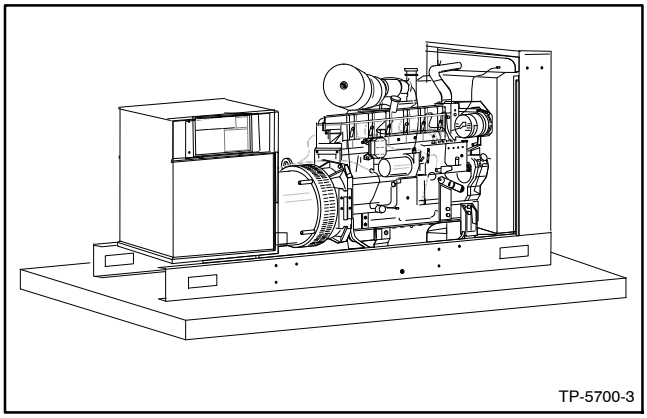


Figure 3-2 Single-Pad Mounting

3.2.2 Dual-Pad Mounting

The two-pad arrangement shown in Figure 3-3 provides easy access to conveniently drain the oil. Follow the oil draining considerations outlined in Section 3.2.1.

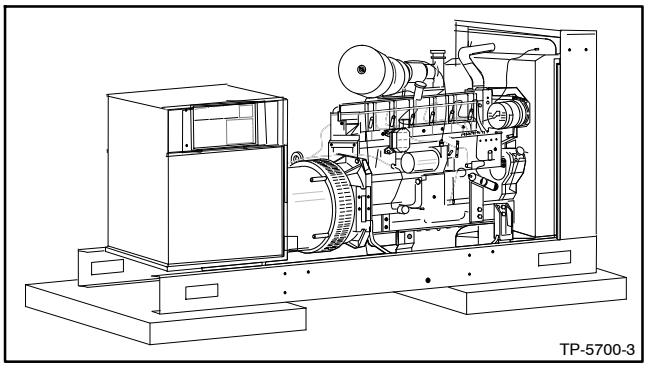

Figure 3-3 Dual-Pad Mounting

3.2.3 Four-Pad Mounting

The four-pad arrangement shown in Figure 3-4 provides more room under the engine for service than the previous two methods. Follow the oil draining considerations outlined in Section 3.2.1.

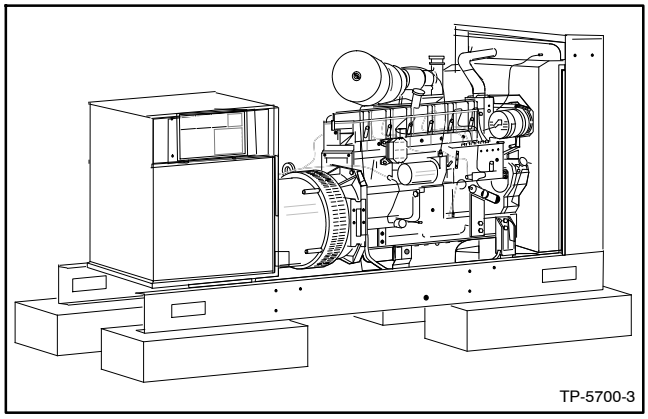

Figure 3-4 Four-Pad Mounting

3.2.4 Mounting Pad Specifications

Mounting pad weight. The weight of the single mounting pad or combined weight of multiple mounting pads should equal or exceed the combined weight of the generator set and attached accessories.

To determine the weight of the mounting pad(s), determine the volume (length x width x height) of each pad in cubic meters (cubic feet). Multiply this result by 2400 kg (150 lb.) to determine a pad's weight. In multiple-pad installations, add the weights of all pads to determine the total mounting pad weight.

Mounting pad specifications. Mounting pad composition should follow standard practice for the required loading. Typical specifications call for 17238–20685 kPa (2500–3000 psi) concrete reinforced with eight-gauge wire mesh or No. 6 reinforcing bars on 305 mm (12 in.) centers. The top surface of the mounting pad on which the generator set mounts should be within a flatness of 3 mm (1/8 in.).

The recommended concrete mixture by volume is 1:2:3 parts of cement, sand, and aggregate, respectively. Surround the pad with a 200–250 mm (8–10 in.) layer of sand or gravel for proper support and isolation of a pad located at or below grade.

Anchor the generator set to the concrete using bolts cast into the surface of the pad. Otherwise, drill holes in the mounting pad prior to generator set placement and use expansion anchor bolts. Anchor the generator set skid or fuel tank (if equipped) using all of the provided anchor holes on the bottom of the skid.

Note: Refer to the generator set and accessory dimension drawings for conduit and fuel-line placement. The drawings give dimensions for electrical and fuel connection roughins and stubups including model specific clearances.

3.3 IBC Seismic Installation

International Building Code (IBC) seismic installations involve additional mounting and installation considerations. Refer to respective seismic installation ADV drawing(s) for seismic isolator requirements.

3.4 Vibration Isolation

Use one of the vibration isolation types detailed in the following paragraphs. Also, connections between the generator set or its skid and any conduits, fuel lines, or exhaust piping must include flexible sections to prevent breakage and to isolate vibration. These connections are detailed in subsequent sections.

Isolator types. The two primary types of isolators are neoprene and spring-type. Figure 3-5 shows neoprene isolators between the engine-generator and the skid, referred to as integral vibration isolation mounting. Integral vibration isolation units come from the factory with neoprene vibration isolation. Neoprene isolators provide 90% vibration isolation efficiency and are often sufficient for installations at or below grade.

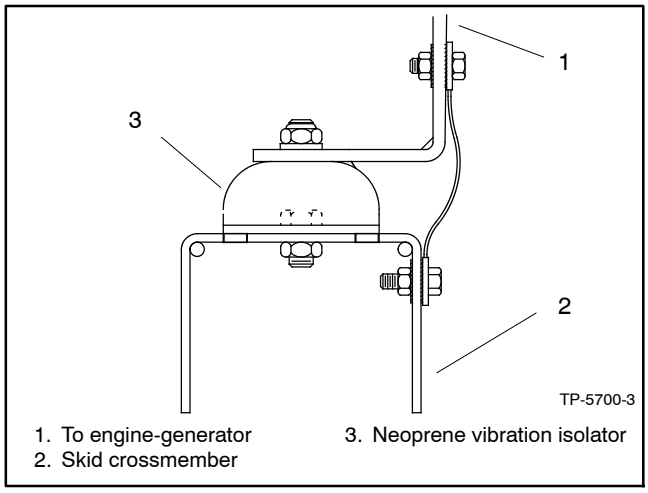

Figure 3-5 Neoprene-Type Integral Vibration Isolators

Figure 3-6 through Figure 3-10 shows the spring-type isolator kit installed *with* direct-mounted units. Direct-mounted units have no factory vibration isolation. Spring-type isolators provide 98% vibration efficiency and are recommended for above grade installations and other locations where vibration sensitivity could be an issue.

Generator sets with integral vibration isolation. Skids for generator sets 20 kW and larger use I or C section-fabricated steel with a width of 52–76 mm (2–3 in.) per channel. The length varies with the size of the unit, resulting in a static load on the generator set skid of 69–172 kPa (10–25 psi) if the total bottom surface of the channel is in contact with the mounting pad.

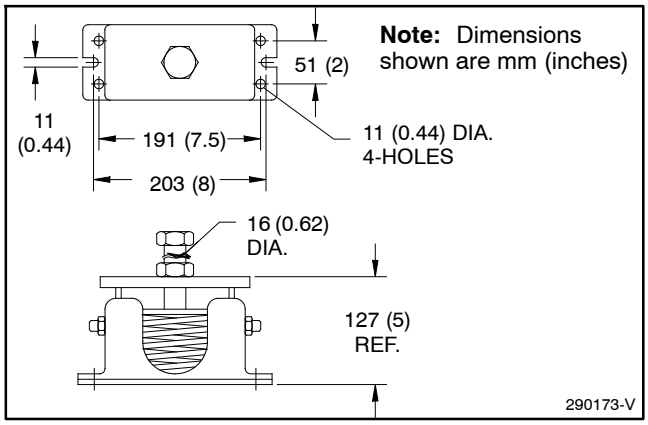

Figure 3-6 Vibration Isolators GM39515 and GM41122

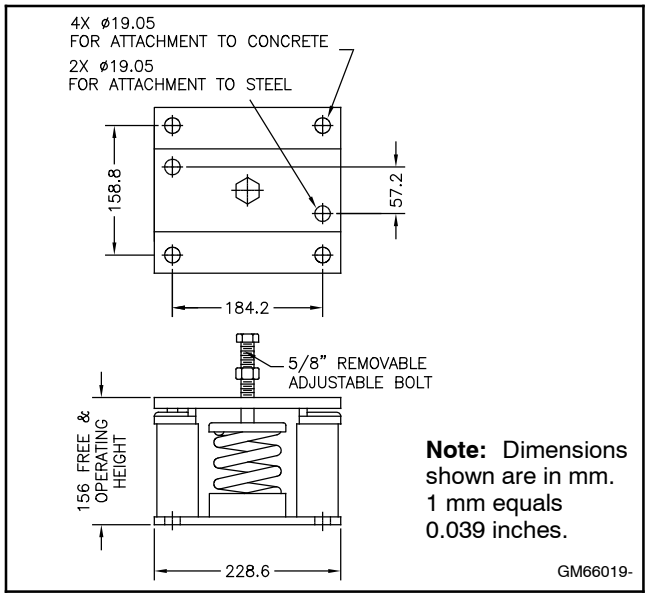

Figure 3-7 Vibration Isolators GM66019, GM66304, and GM76149

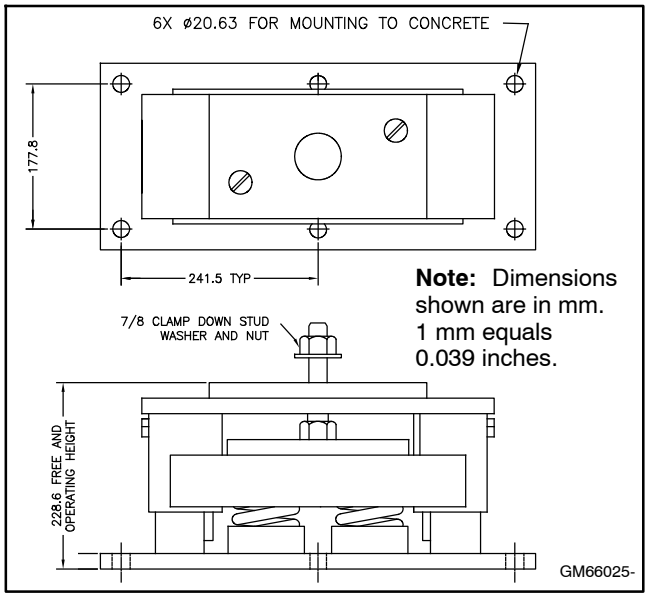

Figure 3-9 Vibration Isolator GM66025

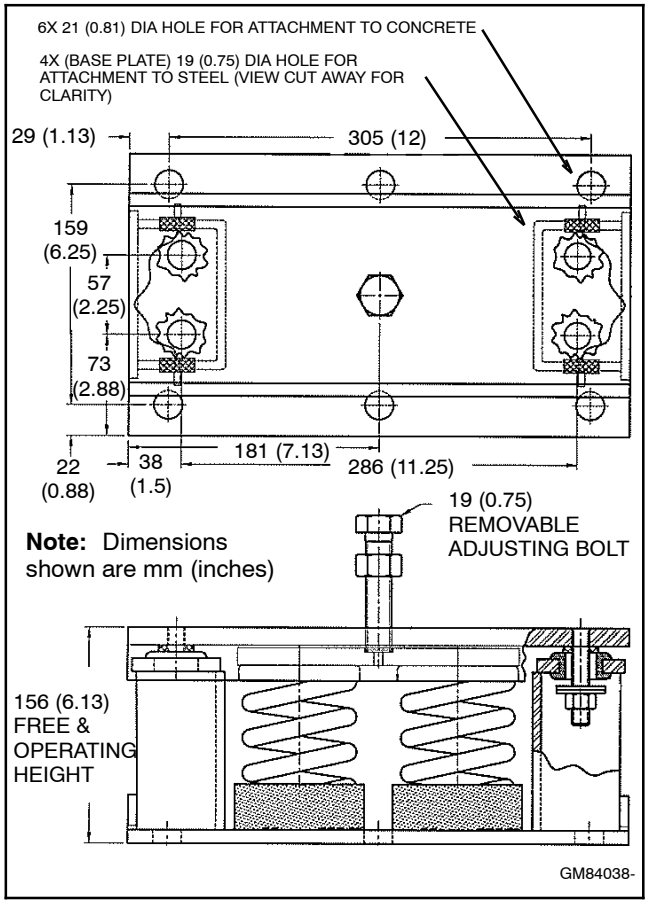

Figure 3-10 Vibration Isolator GM84038

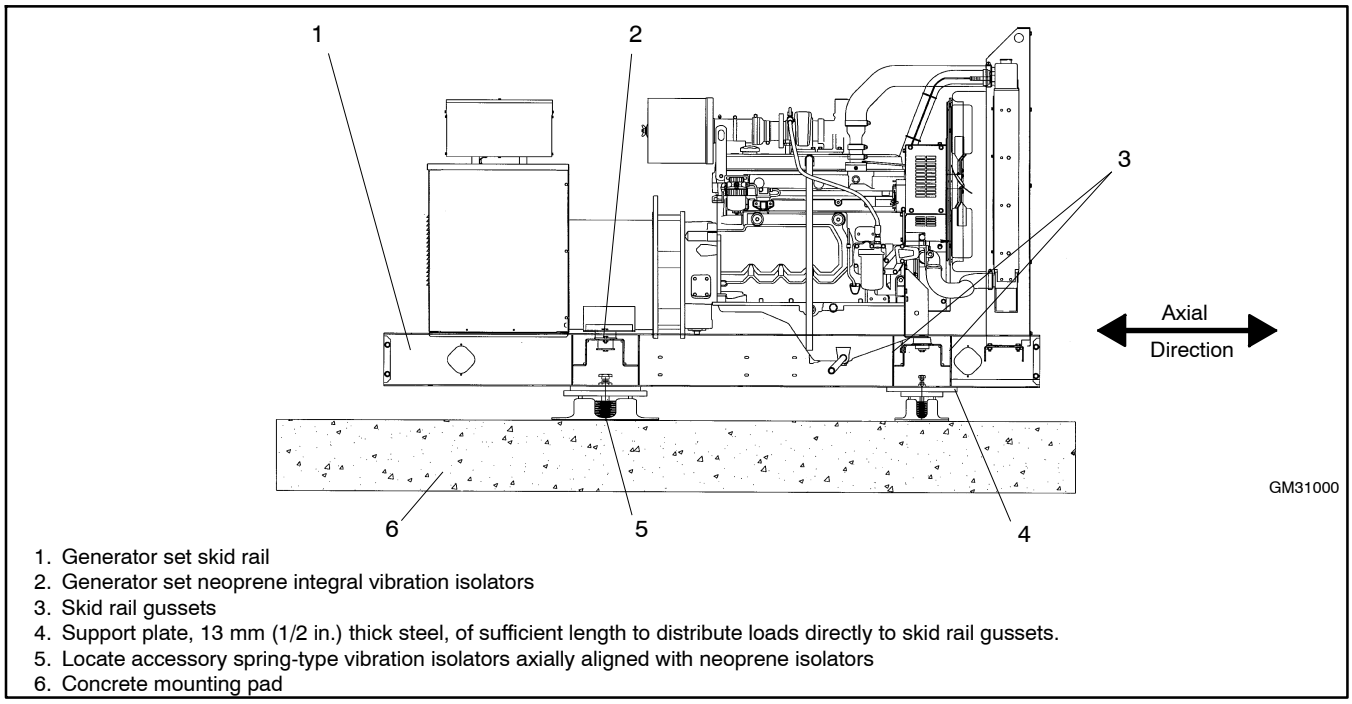
Generator sets with direct mounting. Larger generator sets typically mount directly to a structural steel base. For these units, install the recommended vibration isolators between the base and the mounting pad in the holes provided. Because of the reduced mounting surface area of these individual mounts, the static load on the mounting surface increases to the range of 345–690 kPa (50–100 psi).



Generator sets mounted on subbase fuel tanks. Do not install vibration spring isolators under the subbase fuel tank.

Dual isolation. For applications involving integral vibration isolators and where the factory does not offer spring-type isolators as a standard accessory, spring-type isolators may be installed under the skid provided they equal the number of neoprene isolators, are inline front-to-back with the existing neoprene isolators, and additional support plates are installed, as required. See Figure 3-11.

3.5 Dual-Bearing Alternator Alignment

Generator sets equipped with dual-bearing alternators require alignment after mounting the generator set skid to a mounting pad. Refer to Service Bulletin SB-566 for details.

Note: Dual-bearing alternators used on REZCK model generator sets do not require alignment.

1. Generator set skid rail
2. Generator set neoprene integral vibration isolators
3. Skid rail gussets
4. Support plate, 13 mm (1/2 in.) thick steel, of sufficient length to distribute loads directly to skid rail gussets.
5. Locate accessory spring-type vibration isolators axially aligned with neoprene isolators
6. Concrete mounting pad

Figure 3-11 Accessory Vibration Mount Location

Notes

4.1 General

Combustion and heat dissipation require an ample flow of clean, cool air regardless of whether the generator set is air- or liquid-cooled. Approximately 70% of the heat value of fuel consumed by an engine is lost through the cooling and exhaust systems.

Battery compartment ventilation. To prevent the accumulation of explosive gases, ventilate compartments containing batteries.

4.2 Air-Cooled Engines

Refer to the generator set specification sheet for air requirements. Generally, airflow requirements do not present a problem since air-cooled models are designed for outside installation.

When planning outside installation, consider how buildings and landscaping affect airflow. Also consider seasonal changes such as snow or foliage accumulation and potential flooding conditions. Follow a regular maintenance routine to remove snow and foliage accumulations.

4.3 Liquid-Cooled Engines

4.3.1 System Features

Generator sets designed for interior installation feature liquid cooling systems. The three most common liquid cooling systems are unit-mounted radiator, remote radiator, and city-water cooling. Observe the common installation considerations outlined below as well as the installation considerations for your generator set's cooling system as detailed in subsequent sections.

4.3.2 Installation Considerations

Intake and outlet openings. Provide air intake and air outlet openings for generator sets located in a building or enclosure. Keep air inlets and outlets clean and unobstructed. Position the air inlet into the prevailing wind and the air outlet in the opposite direction.

Elevated outdoor installations. If the generator set enclosure is mounted on multiple pads, in cases where a single pad is not practical such as an uneven building roof, it may cause discharge air recirculation under the unit. Enclosures are constructed with the intent of single pad mounting where the unit is sealed to prevent discharge air recirculation. If multiple pad installation is unavoidable, use a single pad above the multiple pads and fabricate flashing/skirting around the multiple pads to minimize unwanted discharge air recirculation.

Ventilating fans. Some buildings tend to restrict airflow and may cause generator set overheating. Use ventilating fans and/or ductwork to increase airflow in the building if the generator set's cooling fan does not provide adequate cooling. See Figure 4-1. Remote radiator and city-water cooled models require ventilating fans. When using ductwork and ventilating fans, check the exhaust fan capacity in m^3/min. (cfm). If using exhaust fans, install fan-operated louvers with exhaust fans to regulate airflow. See Figure 4-2. Follow the fan manufacturer's recommendations to determine the size of the inlet and outlet openings.

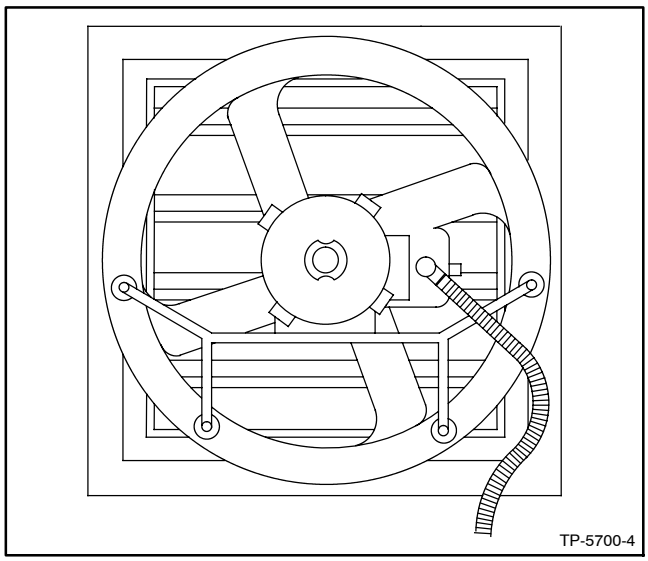


Figure 4-1 Ventilating Fan

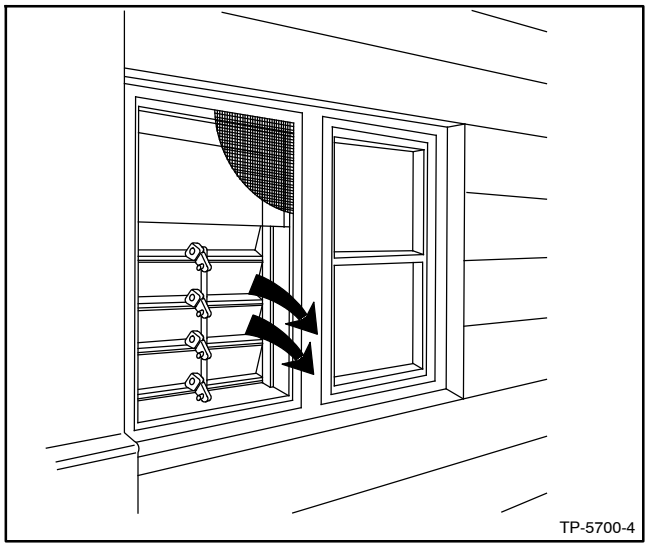

Figure 4-2 Exhaust Fan-Operated Louvers

Thermostatically-controlled louvers. Do not allow uncontrolled recirculation of air within an enclosure. The ventilation system must provide a temperature differential sufficient to prevent high engine temperature shutdown on even the hottest days.

In areas of great temperature variation, install movable louvers to thermostatically regulate airflow and room temperature. See Figure 4-3 and Figure 4-4. Refer to 4.4.2, Installation Considerations, Louver use for further information.

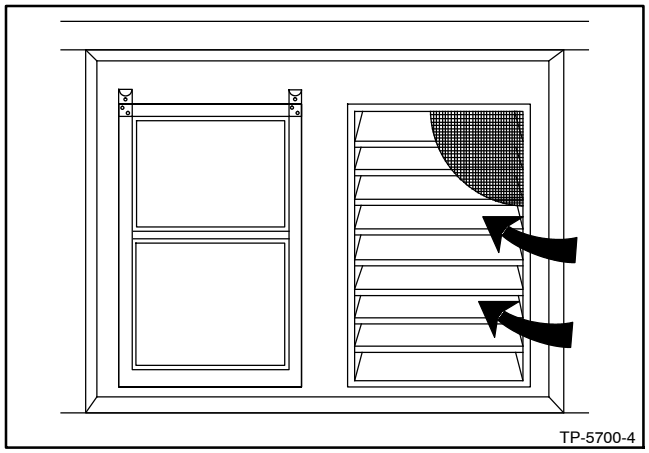

Figure 4-3 Stationary Air Inlet Louvers

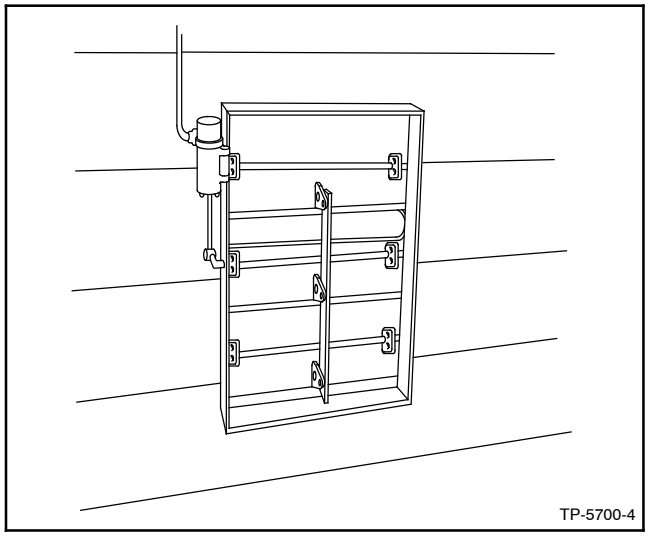

Figure 4-4 Moveable Air Inlet Louvers

In cold climate interior installations using controlled recirculation to recover heat, install thermostatically activated louvers and fans to prevent the generator set and engine room from overheating.

Electric louvers are usually connected to the optional generator set run relay. Typically, the louvers are energized to open when the generator set is operating. However, some louvers are energized to close and when deenergized are spring-actuated to open when the generator set is operating.

Filters. Install a furnace-type or similar filter in the inlet opening if the generator set operates in an atmosphere highly contaminated with impurities such as dust and chaff.

Air restrictions. When using a filter, screen, or other air restriction, increase the inlet opening size by the following amounts to compensate for diminished airflow:

- Louvers**:** Enlarge the opening 50%.
- Window screening: Enlarge the opening 80%.
- Furnace-type filters: Enlarge the opening 120%.

Some engines have maximum air intake restrictions. Refer to the respective generator set specification sheet for specific requirements.

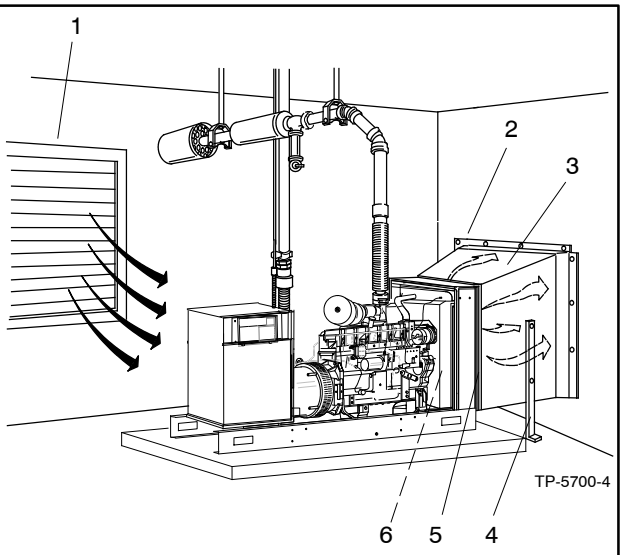
4.3.3 Recommended Coolant

All applications require antifreeze/coolant protection. Add antifreeze/coolant before starting the generator set or energizing the block heater(s). Most diesel engine manufacturers require the use of an inhibitor additive to the antifreeze/coolant.

Use a proper mixture of glycol (ethylene, propylene, or extended life organic acid), water, and supplemental coolant additive (SCA) based on the engine manufacturer's recommendations. The antifreeze/coolant and additive mixture reduces corrosion, sludge formation, and cavitation erosion and provides boil and freeze protection.

Refer to the engine manufacturer's operation manual for engine antifreeze/coolant specifications, concentration levels, and inhibitor selection recommendations.

4.4 Unit-Mounted Radiator Cooling



The unit-mounted radiator is the most common cooling system for engine-driven generator sets 20 kW and larger.

4.4.1 System Features

The system's major components include an engine-driven fan and circulating water pump, a radiator, and a thermostat. The pump circulates water through the engine until it reaches operating temperature. Then the engine thermostat opens, allowing water circulation through the radiator. The thermostat restricts water flow as necessary to prevent overcooling. The fan blows air from the engine side of the radiator across the cooling surface.

4.4.2 Installation Considerations

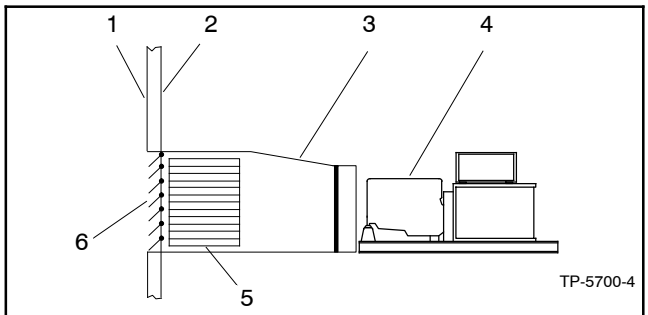
Figure 4-5 shows a typical unit-mounted radiator installation. Note the direction of airflow and refer to the figure as needed during installation.

1. Air inlet opening
2. Ductwork mounting flange
3. Air outlet duct
4. Support legs
5. Flexible section with radiator duct flange
6. Pusher fan

Figure 4-5 Radiator-Cooled Generator Set Installation

Avoid suction fan use. The alternator airflow should move in the same direction as the engine's standard pusher fan. Using a suction fan to reverse airflow is not recommended because it may interfere with the alternator cooling airflow. This in turn reduces the maximum engine power available because higher temperature combustion air is drawn into the air cleaner.

Use ductwork to direct airflow. Direct the radiator air outside the room or enclosure using sheet metal ductwork with structural supports. Keep ductwork as short, straight, and unobstructed as possible. Combined static pressure restrictions greater than 0.12 kPa or 13 mm (0.5 in.) water column on the radiator inlet and outlet openings cause reduced airflow and contribute to overheating especially in high ambient air temperatures. Use heavy canvas, silicone rubber, or similar flexible material for the connection between the radiator duct flange and the ductwork to reduce noise and vibration transmission.



Outlet and inlet location and sizing. Size the outlet duct area 150% larger than the radiator duct flange area. Size the inlet air opening at least as large but preferably 50% larger than the outlet.

If screens, louvers, or filters are used on either the inlet or outlet, increase the inlet or outlet size according to the recommendations given in Section 4.3.2, Installation Considerations.

Since the exhaust air of larger units is both high volume and high velocity, direct the exhaust flow away from areas occupied by people or animals.

Louver use. Design temperature-controlling louvers to prevent air inlet restrictions and air pressure reductions inside the building. Low building pressure can extinguish pilot lights on gas-fired appliances or cause problems with the building ventilation system.

Additionally, bringing large quantities of winter air into a building wastes building heat and risks frozen water pipes in normally heated spaces. Use dampers and controlled air outlet louvers as shown in Figure 4-6 to eliminate these problems and allow recovery of engine heat to reduce building heat loss. Close the louvers to the exterior and open the interior louvers when the outdoor temperature is below 18°C–21°C (65°F–70°F). Reverse the louver settings when the outdoor temperature is above 21°C–24°C (70°F–75°F).

Figure 4-6 Air Control Louvers

4.5 Remote Radiator Cooling

A remote radiator system allows installation of generator sets in locations where it would otherwise be difficult to bring the volume of air required to cool a unit-mounted radiator. In these systems, the engine water pump pushes coolant through a radiator mounted remotely from the generator set and, typically, in an open area. An electric motor-driven fan mounted on the radiator circulates air across the radiator's cooling fins.

The remote radiators have a Secondary Expansion Deaeration and Drawdown (SEDD) tank. This SEDD tank can be connected to the radiator either as an open or closed tank system. Closed SEDD tanks are typically used when the remote radiator is in close proximity to the generator set and open SEDD tanks are typically used when the remote radiator is located further away.

In order to assess a remote radiator cooling system, the cooling system designer needs the following data. From the respective generator set specification sheet, obtain the:

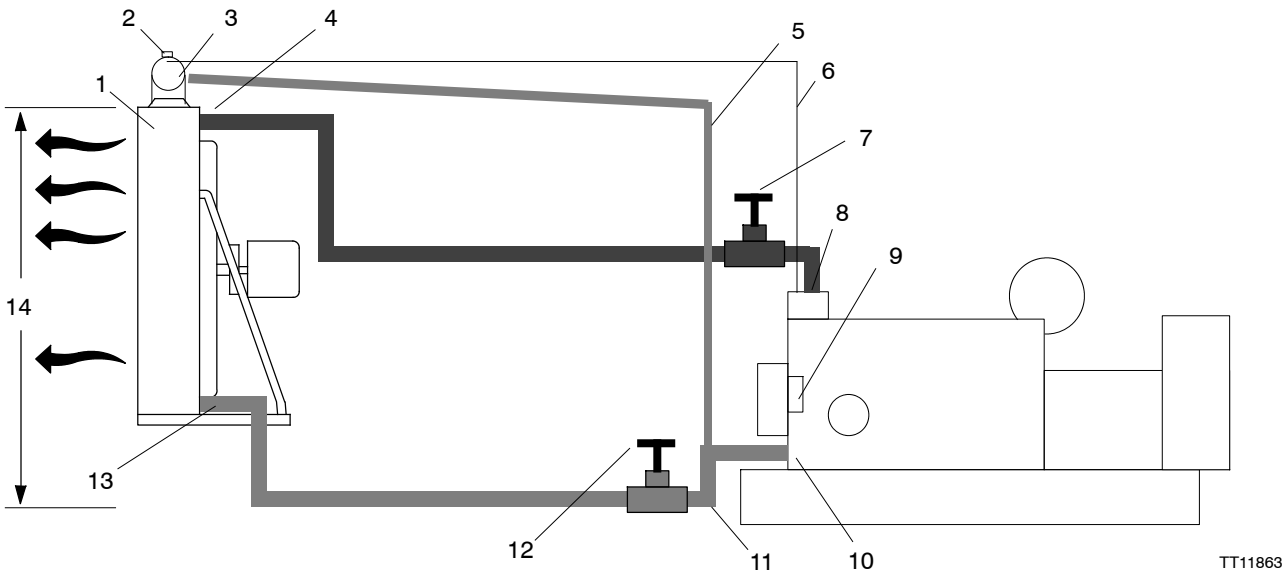
- Engine jacket water flow, Lpm (gpm)
- Cooling air required for generator set based on 14°C (25°F) rise and an ambient temperature of 29°C (85°F), m^3/min. (cfm)
- Maximum static (vertical) head allowable above engine, kPa (ft. H_2O)

From the engine and/or radiator data sheet, obtain the:

- Maximum water pump inlet restriction kPa (psi)
- Maximum allowable coolant pressure differential external to engine kPa (psi)

Note: The REZCK models are not equipped with an engine-driven water pump and primary/secondary thermostats. Selection, sourcing, and installation of the primary/secondary water pumps and primary/secondary thermostats must be provided by the design engineer based on the application requirements using the generator set spec sheet data and the water pump manufacturer's specifications.

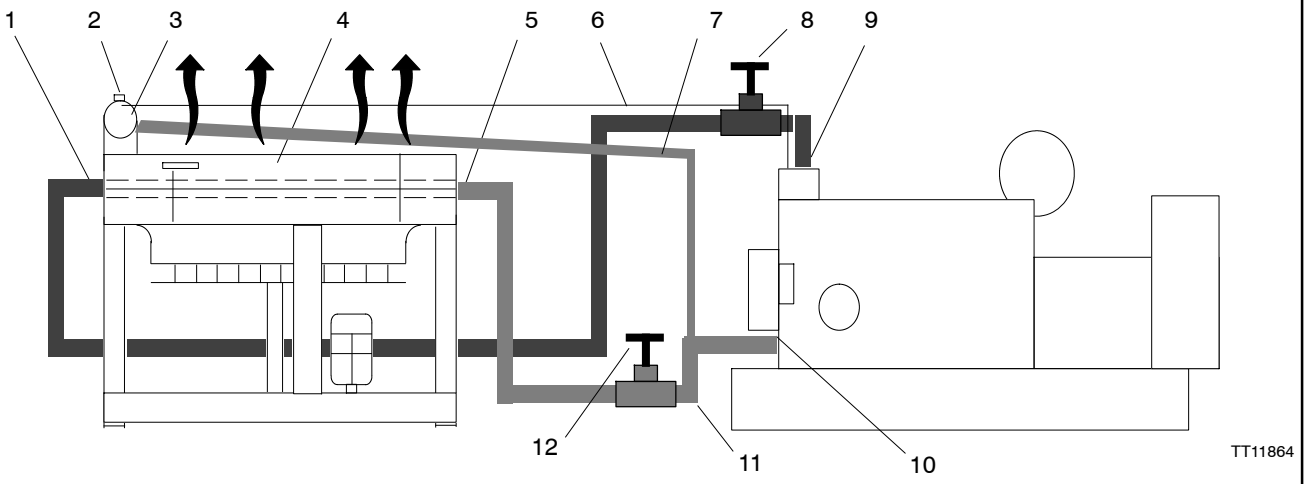
The following subsections provide general design guidelines for a remote radiator system.



4.5.1 General

System limitations. Cooling systems are limited by radiator cap ratings. The maximum radiator operating pressure is 138 kPa (20 psi) and the maximum operating temperature is 121°C (250°F). Radiators are available for vertical or horizontal discharge. See Figure 4-7 and Figure 4-8.

Air requirements. Refer to the generator set specification sheet for radiator air and engine/alternator air requirements. Cooling air required for generator sets equipped with a remote radiator is based on a 14°C (25°F) rise and an ambient temperature of 29°C (85°F). The amount of air required to ventilate the generator set room or enclosure determines the size of the air inlet and outlet. Configure the ventilation air inlet and outlet so that air flows across the generator set.



Use a ventilating fan, if necessary, to dissipate alternator and engine heat loss.

Note: All remote radiators are sized for mounting in an open area with no additional external devices attached. Attached devices, confined installation, louvers, dampers, ductwork, or other inlet or outlet air restriction require resizing the radiator to compensate for reduced airflow.

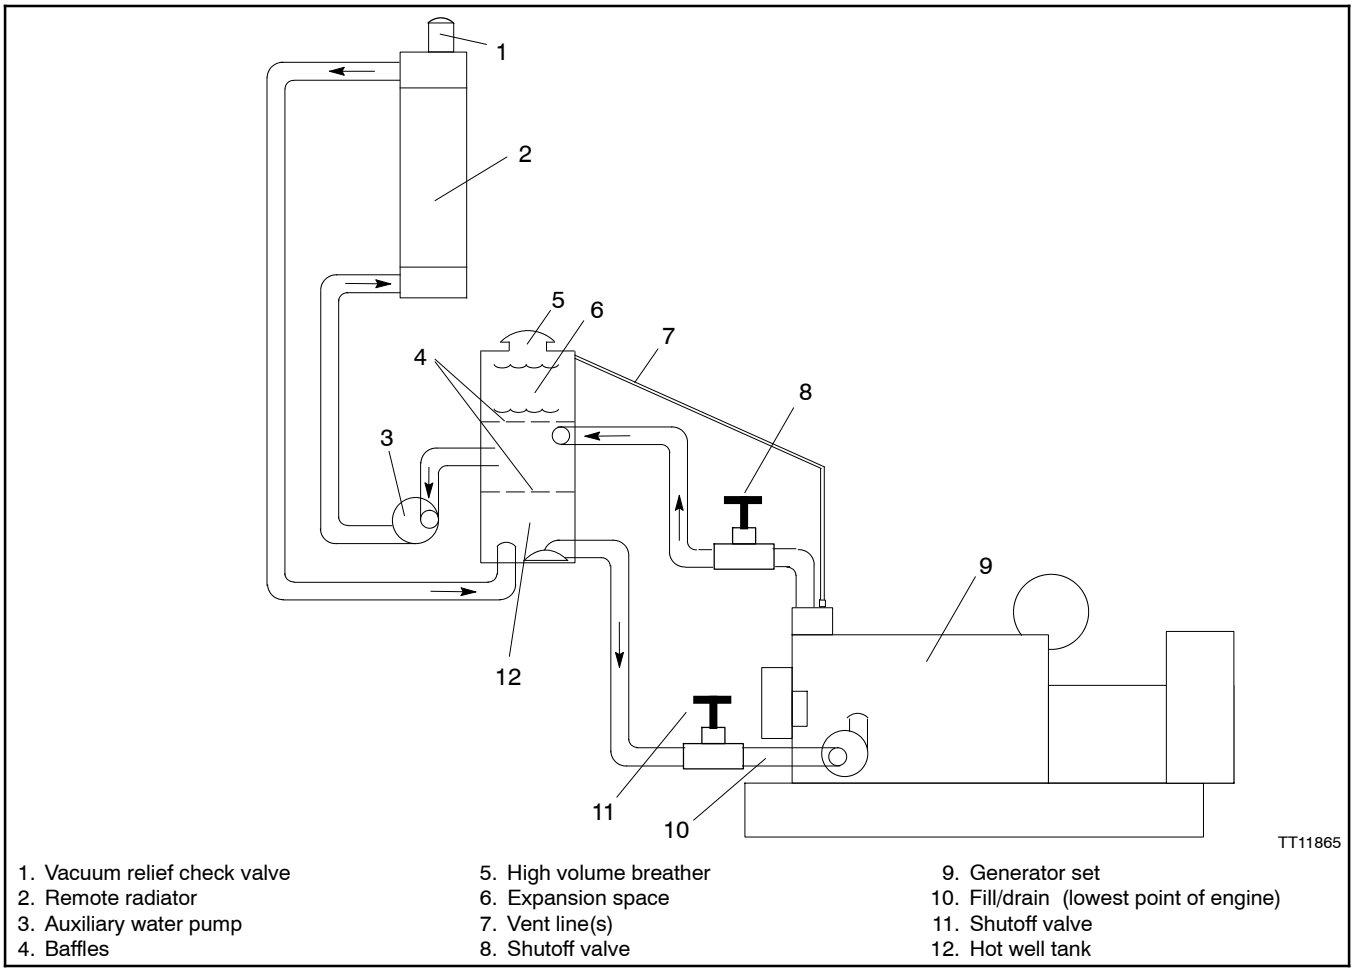
Static (vertical) head. If the vertical distance from the engine water pump to the radiator (known as *static head*) is within the engine manufacturer's recommendations, and the pressure drop through the piping and remote radiator does not exceed the engine manufacturer's limits, use the engine water pump to circulate water through the remote radiator. The allowable static head ranges from 5.2 m–15.2 m (17 ft.–50 ft.) and is listed on the generator set specification sheet. Exceeding the allowable static head causes excessive pressure on engine components resulting in problems such as leaking water pump seals.

Note: Size the pressure relief valve or cap to remain under the engine pressure limit.

Hot well tank/heat exchanger. When the static (vertical) head exceeds the distance stated in the specification sheet, use a hot well tank or heat exchanger and auxiliary circulating pump as shown in Figure 4-9 or Figure 4-10. Always wire the circulating pump in parallel with the remote radiator fan so that both operate whenever the generator set operates.

A partial baffle divides a hot well tank into two or more compartments. The engine pump forces heated water into the hot side, and the auxiliary pump then draws the water off and forces it into the radiator. After circulating through the radiator, coolant drains back to the cold side of the well where the engine water pump removes it. A hot well or heat exchanger also isolates head pressures from the engine.

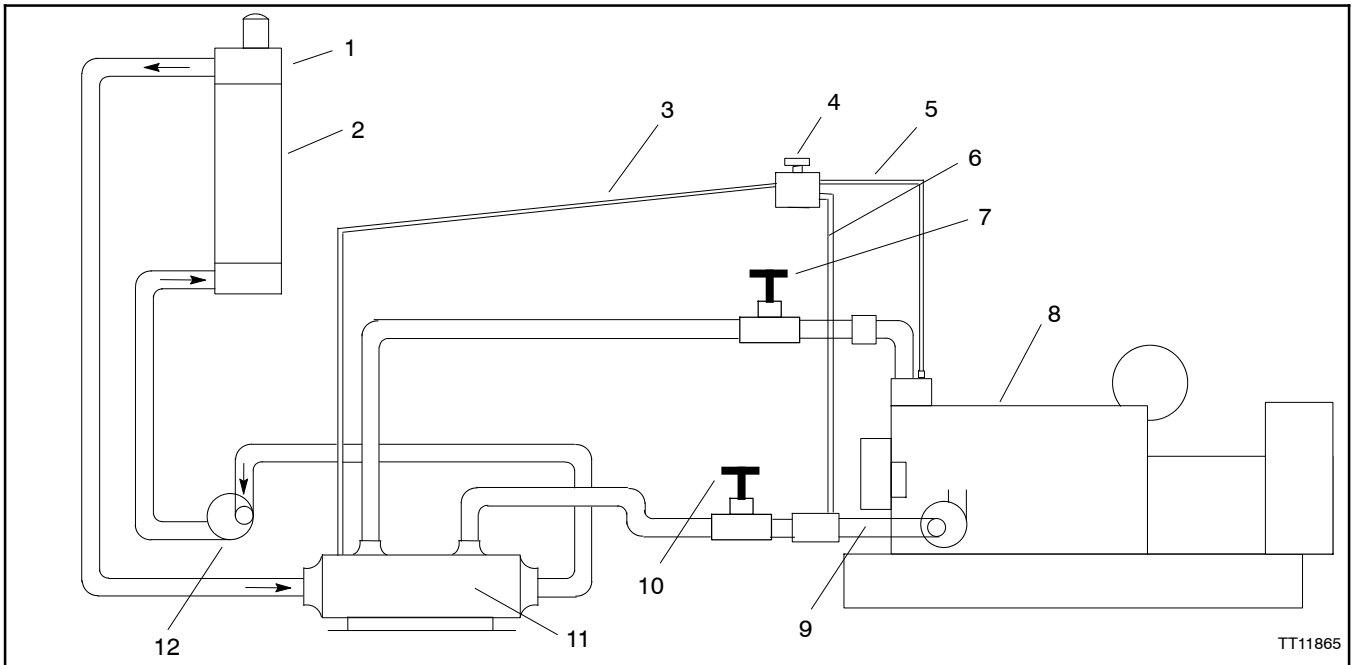
Note: The water in the hot well tank drains into the radiator when the generator set is not running.



Note: Determine the size requirements of the remote radiator and hot well tank/heat exchanger for each application. Do not use a standard remote radiator with a hot well tank/heat exchanger.

4.5.2 Vent Lines

Route the vent lines at a continuous upward slope from the engine connection exit to the expansion tank. Port all vent lines individually into the expansion tank above the coolant level.



Locate the vent lines in the expansion tank to prevent splash on the coolant level sensor. Thoroughly vent the systems by installing vent lines to all the vent points on the engine and the charge air cooler circuits including the radiator core. Refer to the installation drawings for vent points.

Size the vent line the same as the connection point on the engine. The vent lines may be slightly larger; however, vent lines sized too large will increase fill line flow and possibly reduce head pressure applied to the engine water pump inlets.

4.5.3 Fill Lines (Balance or Static)

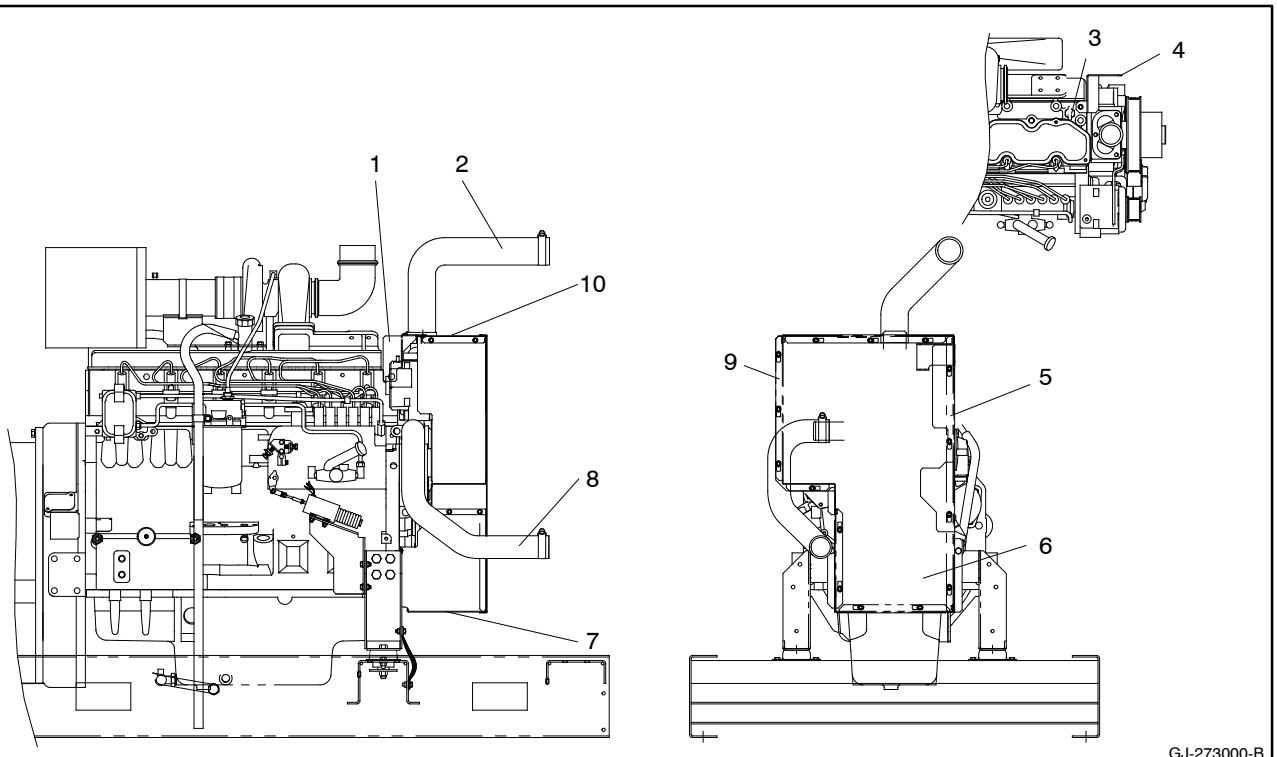
Connect the fill line(s) to the bottom of the expansion tank. Make the lines as short as possible, continuously descending, and connected directly *before* the engine water pump(s). To provide a positive head pressure to the engine water pump inlet, properly locate the fill line (or makeup line). See the installation drawings for the fill line connection points.

Connect the vent and fill lines to the expansion tank at the greatest possible distance from each other to prevent aeration and preheating of the coolant returning down the fill line.

The minimum fill line sizes cannot be smaller than the connection point on the engine. Do not allow fittings on the fill lines to reduce the effective size. If other cooling system components vent too much coolant to the expansion tank, larger diameter fill lines may be needed.

4.5.4 Location Considerations

When choosing the radiator's location:



- For economical installation and operation, locate the radiator as close as practical to the engine and at the same elevation to reduce piping, coolant, and wiring costs.
- Locate the radiator surge tank fill opening and vent line(s) at the highest point in the cooling system.
- Position the radiator no closer than one fan diameter from a wall, another radiator, or any other obstruction that would restrict air movement and future service access.
- Locate the radiator to prevent recirculation of the heated exhaust air back into the intake stream.
- Mount the radiator in an area where prevailing winds do not hamper free airflow.
- Locate the radiator where it is not subject to deep snow or ice accumulation, flooding, industrial fallout, leaf accumulation, heavy dust and chaff, or other detrimental seasonal or environmental conditions.
- For rooftop installations, do not locate the radiator near critical sound areas, building ventilation, or hood exhausts.

4.5.5 Installation Considerations

Note: The REZCK models are not equipped with an engine-driven water pump and primary/secondary thermostats. Selection, sourcing, and installation of the primary/secondary water pumps and primary/secondary thermostats must be provided by the design engineer based on the application requirements using the generator set spec sheet data and the water pump manufacturer's specifications.

When installing the remote radiator:

- Use a remote radiator setup kit, if available, to aid installation. See Figure 4-11.
- Wire the cooling fan motor to the generator set output so that the fan operates whenever the generator set operates. There is no need for a thermostatic control of the fan motor because the engine thermostat prevents overcooling as it does on generator set-mounted radiator systems. Follow all applicable national and local codes when wiring the cooling fan.
- Follow the wiring diagram on the remote radiator's fan motor. The motor rotation must match the fan blade design. The manufacturer supplies most units with counterclockwise fan rotation as viewed from motor side. The fan is a blower type, moving air from the fan side of the radiator, through the core, and out the front side.
- Preferably, connect no devices to either side of the radiator. Resize the radiator if adding louvers or duct work to the radiator to compensate for reduced airflow.
- Ensure that the radiator is level and securely bolted to a firm, solid foundation.
- Brace the radiator as needed, especially in areas with strong winds.
- Use isolators to keep area vibration from affecting the radiator or to keep vibration produced by the radiator from affecting surrounding areas.
- Use hose clamps on all nonthreaded connections.

4.5.6 Surge (Expansion) Tank for Horizontal Discharge Radiator

A horizontal discharge remote radiator requires the use of a surge (expansion) tank as shown in Figure 4-7. Locate the tank at the highest point in the cooling system. The surge tank provides venting, surge/expansion protection, and filling/makeup functions.

- Equip the surge tank with a sight-glass gauge, overflow tube, and pressure cap.
- Size the surge tank to handle at least 6%–10% of the total cooling system volume. Follow the engine manufacturer's recommendation when available.
- Connect the main line from the surge tank to the highest point of the remote radiator. Most vertical core radiators have the surge tank as part of the radiator top tank. The setup illustrated in Figure 4-7 provides for radiator and engine deaeration and a positive pressure at the pump suction inlet.
- Use a strainer to filter dirt, scale, and core sand from the coolant line.

Piping. Size water piping between the engine and the remote radiator large enough to eliminate the need for a booster pump. If the cooling system requires a booster pump, contact your distributor/dealer.

Use piping of ample size and with as few short sweep bends or elbows, tees, and couplings as possible. Use long sweep elbows or long bends, if bends are required.

Installation. Support piping externally, not from the radiator or engine.

On standard remote radiators, connect radiator bottom outlets only to the suction side of the pump. Plumb the lines to prevent air from becoming trapped in the lines. Route piping in one general direction, either upward or downward. A combination of both upward and downward piping creates air pockets in the piping. Route vent lines to the expansion/surge tank without creating low spots in the lines.

Flexible connections. Provide flexible connections when connecting piping to the radiator assembly. Use hose clamps at all nonthreaded connections.

Shutoff valves. Locate shutoff valves between the engine and cooling system to allow for isolation of both the radiator and the engine. A shutoff valve eliminates the need to drain the entire cooling system during service.

4.5.7 Procedure to Fill with Deaeration

For radiators designed for full deaeration, fill the radiator according to the following procedure.

1. Fill the cooling system from the bottom when possible. Otherwise, fill the radiator at the filler neck.
2. Next, fill the radiator through one of the top tank or expansion/surge tank inlets located before the final hose connection.
3. Continue filling the system to cover the filler neck bottom until coolant appears in the sight glass located in the radiator top tank.
4. Check and correct any leaks in the system.

4.5.8 Procedure to Fill without Deaeration

For radiators designed without deaeration, fill the radiator according to the following procedure.

1. Initially, fill the radiator through one of the top tank inlets located before the final hose connection for faster and more complete fillup.
2. Fill the cooling system from the bottom when possible. Otherwise, fill the radiator at the filler neck with coolant covering the filler neck bottom until coolant appears in the sight glass located in the radiator top tank.
3. Check for and correct any leaks in the system.

4.5.9 Checks after Initial Startup

If any problems arise during startup, immediately shut down the generator set. See Figure 4-12, Cooling System Checklist. Even after a successful startup, shut down the generator set after 5–10 minutes and recheck the belt tension to make sure no hardware has loosened during operation. Perform another recheck after 8–12 hours of operation.

✓	**Operation**
	Verify the cooling fan's position in the fan shroud.
	Check the mounting hardware.
	Check the fan motor for free rotation.
	Check V-belts for alignment and tension.
	Fill the system with coolant and check all connections for tightness and leaks.
	Verify that all electrical connections are secure and that the power source matches the motor nameplate.
	Verify that no loose foreign material is in the fan's air stream.
	With the unit running, check for:
	fan clearance
	excessive vibration
	excessive noise
	coolant leaks

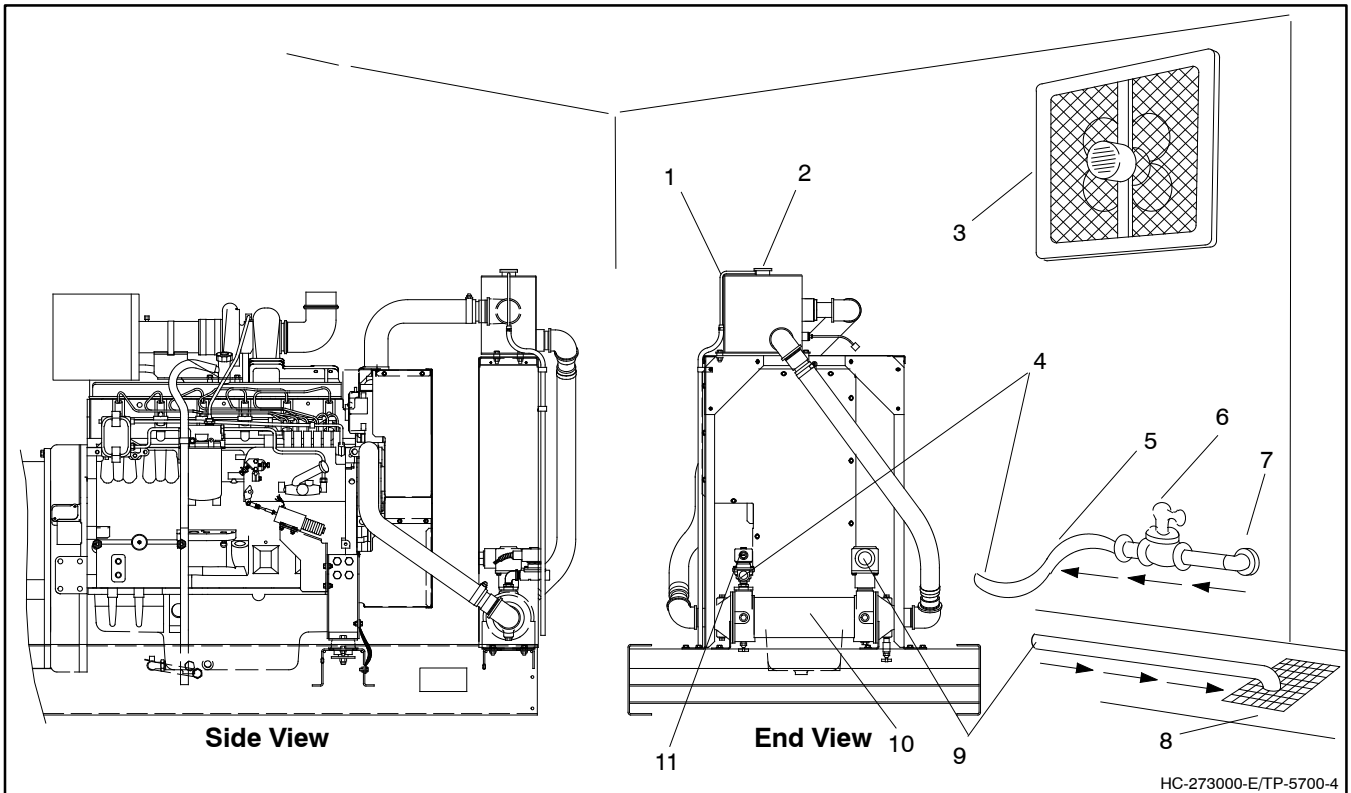
4.6 City Water Cooling

4.6.1 System Features



City water-cooling systems use city water and a heat exchanger for cooling. They are similar to remote radiator systems because they require less cooling air than unit-mounted radiator systems. Figure 4-13 shows some of the elements of a typical installation.

The heat exchanger limits the adverse effects of city water chemistry to one side of a heat exchanger, which is relatively easy to clean or replace, while engine coolant circulates in a closed system similar to the radiator system. The heat exchanger allows engine temperature control, permits the use of antifreeze and coolant conditioners, and is suited to the use of an engine block heater as a starting aid.

4.6.2 Installation Considerations

Vibration isolation requirements. Water inlet and outlet connections are mounted on the generator set skid and isolated from engine vibration by flexible sections. If the generator set is vibration-mounted to the skid and the skid is bolted directly to the mounting base, no additional flexible sections are needed between connection points on the skid and city water lines. If the generator set skid is mounted to the base with vibration isolators, use flexible sections between the connection points on the skid and city water lines.

Shutoff valve location. A solenoid valve mounted at the inlet connection point automatically opens when the generator set starts, providing the engine cooling system with pressurized water from city water mains. This valve automatically closes when the unit shuts down. Use an additional customer-supplied valve ahead of the entire system to manually shut off city water for generator set service.

4.7 Cooling Tower

A cooling tower system is a variation of a city water cooling with heat exchanger system. In warm, dry climates, a cooling tower is a suitable source of generator set cooling water.

A cooling tower system consists of the engine cooling system plus a raw-water system. The engine cooling system usually includes the engine water pump, a heat exchanger, a surge tank, and the engine water jacket. The raw-water system consists of the cooling tower, a raw-water pump, and the tube portion of the heat exchanger. A typical system is shown in Figure 4-14.

The engine cooling system circulates coolant through the heat exchanger outer shell. Raw water circulates through the heat exchanger tubes absorbing heat from the engine coolant. The heated raw water flows into a pipe at the top of the cooling tower and sprays down into the tower to cool by evaporation. Because some water is constantly being lost through evaporation, the system must provide makeup water.

4.8 Block Heaters

Block heaters are available as installed accessories on all generator sets. Generator sets installed in NFPA applications generally require use of a block heater. Equip generator sets with block heaters on all standby applications where the generator set is subject to temperatures below 0–20°C (32–68°F). See the respective generator set spec sheet for specific temperature recommendations. Connect the block heater to a power source that is energized when the generator set is not running. The block heater thermostat temperature is set for optimum operation based on the respective engine cooling characteristics.

Note: Block heater damage. The block heater will fail if the energized heater element is not immersed in coolant. Fill the cooling system before turning on the block heater. Run the engine until it is warm and refill the radiator to purge the air from the system before energizing the block heater.

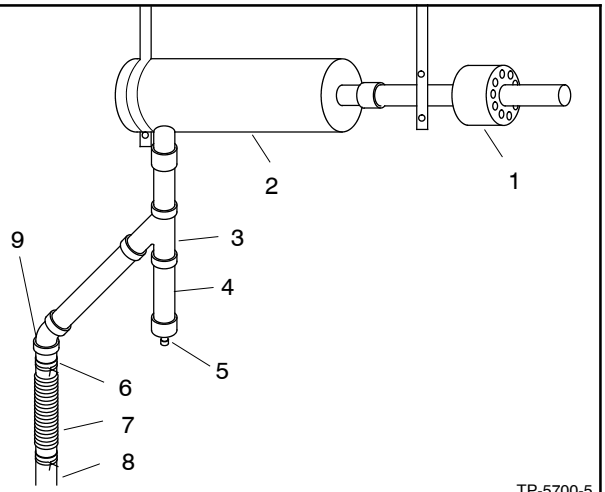
Notes

Satisfactory generator set performance requires proper exhaust system installation. Figure 5-1 and Figure 5-2 show typical arrangements of recommended exhaust systems. The following sections detail exhaust system components.



5.1 Flexible Exhaust Line

Install a section of seamless stainless steel flexible exhaust line at least 305 mm (12 in.) long within 610 mm (2 ft.) of the engine exhaust outlet. See Figure 5-1 and Figure 5-2.

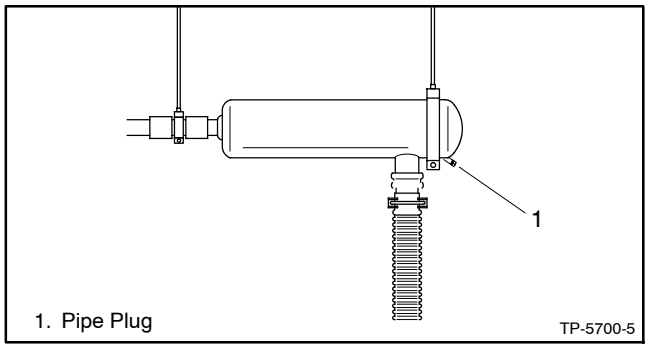
9. 45° elbow

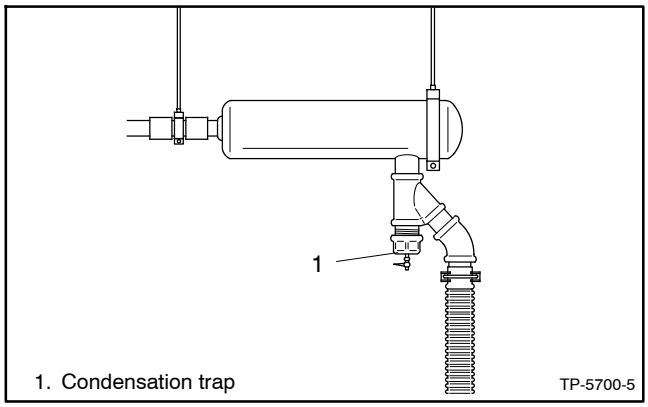
Figure 5-2 Exhaust System, Side Inlet Silencer



The flexible line limits stress on the engine exhaust manifold or turbocharger. Never allow the engine manifold or turbocharger to support the silencer or exhausting piping.

Note: Do not bend the flexible section or use it to compensate for misalignment between the engine exhaust and the exhaust piping.

When using threaded flexible exhaust connectors, place a 152–203 mm (6–8 in.) length of pipe between the flexible exhaust connectors and the exhaust manifold. See Figure 5-1. The pipe reduces the temperature of the flexible connection, simplifies flexible section removal, and reduces strain on the engine exhaust manifold.



5.2 Condensation Trap

Some silencers are equipped with a drain pipe plug for draining condensation; see Figure 5-3. Otherwise, install a wye- or tee-type condensation trap with a drain plug or petcock between the engine and the exhaust silencer as shown in Figure 5-4. The trap prevents condensed moisture in the engine exhaust from draining into the engine after shutdown. Periodically drain collected moisture from the trap.

1. Pipe Plug

Figure 5-3 Silencer Condensation Drain Plug

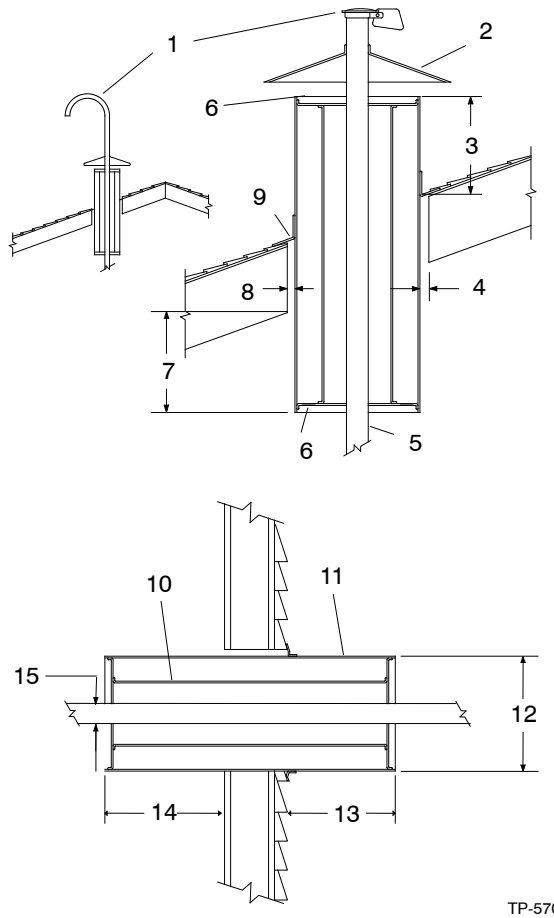
1. Condensation trap

Figure 5-4 Condensation Trap

5.3 Piping

Note: Select piping with a diameter that is the same size as, or larger than, the manifold outlet's inside diameter.

- Keep exhaust lines as short and straight as possible.
- Use schedule 40 black-iron pipe.
- Use sweep elbows with a radius of at least three times the pipe diameter.
- Use exhaust piping that conforms to applicable codes.
- Support the exhaust piping securely, allowing for thermal expansion.
- Insulate the exhaust piping with high-temperature insulation to reduce the heat rejected by exhaust piping and consequently the amount of ventilating air required.



In general, exhaust temperatures measured at the engine's exhaust outlet are less than 538°C (1000°F), except for infrequent brief periods; therefore, low-heat appliance standards apply. Each generator set specification sheet provides exhaust temperatures.

For units with exhaust temperatures below 538°C (1000°F), route the exhaust piping a minimum of 457 mm (18 in.) from combustible material, including building materials and natural surroundings. If exhaust temperatures exceed 538°C (1000°F), the minimum distance is 914 mm (36 in.).

When planning exhaust silencer and piping placement, consider the location of combustible materials. If the proximity of the exhaust system to the combustible materials cannot be avoided, follow a regular maintenance schedule to ensure that combustible materials are kept away from the exhaust pipes after installation. Combustible materials include building materials as well as natural surroundings. Keep dry field grass, foliage, and combustible landscaping material a safe distance from the exhaust system.

5.4 Double-Sleeved Thimbles

If the exhaust pipe passes through a wall or roof, use a double-sleeved exhaust thimble to prevent the transmission of exhaust pipe heat to the combustible material. Figure 5-5 shows construction details of a typical double-sleeved thimble in which exhaust piping passes through a combustible structure. Sheet metal shops usually fabricate thimbles using installation engineer's specifications and drawings.

13. 254 mm (10 in.) minimum outside
14. 254 mm (10 in.) minimum inside
15. Exhaust pipe diameter

Figure 5-5 Double-Sleeved Thimbles and Rain Cap

Construct the thimble so it extends at least 254 mm (10 in.) both inside and outside the structure's surface. Openings at both ends of the thimble allow cooling air to circulate through the thimble. If screening is used on the outer end to keep birds and animals from entering the thimble, use a mesh large enough to allow unrestricted air circulation through the thimble. See Section 5.5 for additional exhaust outlet location and protection considerations.

5.5 Exhaust Outlet

Outlet location. Engine performance and efficiency depend on the location of the exhaust outlet. Direct the exhaust outlet away from the air inlet to prevent exhaust gases from entering the air inlet and clogging the dry-type air filter elements. Hot exhaust drawn through the radiator adversely affects engine cooling. Locate the exhaust outlet to prevent exhaust fumes from entering a building or enclosure.

Noise reduction. The exhaust outlet configuration affects the apparent noise level for people or animals in the vicinity. An upward-directed outlet seems quieter than one directed downward or horizontally. Additionally, a 30- to 45-degree angled cut at the end of a horizontal exhaust outlet pipe reduces turbulence at the outlet, thereby reducing the noise level.

Rain cap. To prevent precipitation from entering the exhaust pipe, install a rain cap on vertical outlets. See Figure 5-5. In a climate where freezing is common, do not use a rain cap. Instead, extend the exhaust piping at least 610 mm (24 in.) beyond the roof line and create a gradual U bend at the end to direct the exhaust outlet downward. Keep the pipe outlet at least 457 mm (18 in.) from the roof to prevent hot exhaust from igniting the roof material.

Note: Do not use a rain cap in areas subject to freezing temperatures.

Generator set with enclosure. To avoid exceeding the engine manufacturer's maximum allowable backpressure specification, enclosure tail pipe extensions or attachments are not recommended.

5.6 Exhaust System Backpressure

Exhaust backpressure limits engine power and excessive backpressure causes serious engine damage. Excessive backpressure usually results from one or more of the following reasons:

- The exhaust pipe diameter is too small.
- The exhaust pipe is too long.
- The exhaust system has too many sharp bends.
- The exhaust silencer is too small.
- The exhaust silencer is not the correct design for the application.

Use the following procedure to verify that the installed exhaust system does not exceed the engine's maximum exhaust backpressure limit as specified in the generator set specification sheet.

Exhaust System Backpressure Calculation Procedure

Determine the total backpressure by calculating the effects of the individual exhaust system components and adding the results. Make calculations using either English or metric units. Exhaust pipe references are nominal pipe NPT (in.) sizes. The procedure shows an example with *italic* text. Calculations relate to end inlet silencers.

Note: When calculating backpressure drop for *side* inlet silencers, use the *end* inlet values shown and add 0.75 kPa (0.25 in. of mercury or 3.4 in. of water) to backpressure calculations.

1. Select the exhaust silencer type for the application—hospital, critical, residential, or industrial. See the silencer specification sheet for definitions for each exhaust silencer type. Confirm silencer type availability for your generator set with your authorized distributor/dealer, as some generator sets do not use all four types.

   Example: Determine the silencer backpressure for the recommended critical silencer on a 230 kW, 60 Hz diesel generator set.

2. Refer to the generator set specification sheet for:

   a. Engine exhaust flow at rated kW in m^3/min. (cfm)

      Example: 57.5 m^3/min. (2030 cfm)

   b. Maximum allowable backpressure in kPa (in. of Hg)

      Example: 10.2 kPa (3.0 in. Hg)

3. Refer to the submittal catalog for:

   a. The recommended critical silencer part number
      Example: 343616

   b. Silencer inlet diameter in mm (in.)
      Example: 152 mm (6 in.)

   c. Silencer inlet position (end or side)
      Example: end inlet

   d. The flexible exhaust adapter part number
      Example: 343605

   e. Flexible exhaust adapter, flexible section length
      Example: 857 mm (33.75 in.)

4. Determine the exhaust gas velocity through the silencer as follows:

   a. Using the exhaust silencer inlet diameter determined in step 3, determine corresponding inlet area using Figure 5-6.

      Example: 0.0187m^2 (0.201 sq. ft.)

   b. Use this data to calculate the exhaust gas velocity. Divide the engine exhaust flow from step 2 in m^3/min. (cfm) by the silencer inlet area m^2 (sq. ft.) to get flow velocity in m (ft.) per minute.

      Example:
      57.5 m^3/min. / 0.0187 m^2 = 3075 m/min.
      (2030 cfm / 0.201 sq. ft. = 10100 ft./min.)

Nominal Pipe Size, in. NPT	Inlet Area, m^2	Inlet Area, ft^2

16	0.1140	1.227
18	0.1442	1.553

Figure 5-6 Cross Sectional Area for Standard Silencer Sizes

5. Refer to Figure 5-7. Use the exhaust gas velocity determined in step 4 and find the exhaust gas velocity value in thousands on the bottom scale. Move vertically up until this value intersects the curve of the corresponding silencer type as determined in step 1. Move left on the horizontal axis and determine the backpressure drop value in kPa (in. of Hg).

   Example: Exhaust velocity, 3075 m/min. (10100 ft./ min.) intersects with critical silencer curve B and the corresponding backpressure value is approximately 2.8 kPa (0.85 in. of mercury). Silencer type is end inlet from step 3 information with no additional backpressure drop value per the following note.

   Note: When calculating backpressure drop for *side* inlet silencers, use the *end* inlet values shown and add 0.75 kPa (0.25 in. of mercury or 3.4 in. of water) to backpressure calculations.

   Note: Refer to Figure 5-8 to calculate in inches of water and feet per minute.

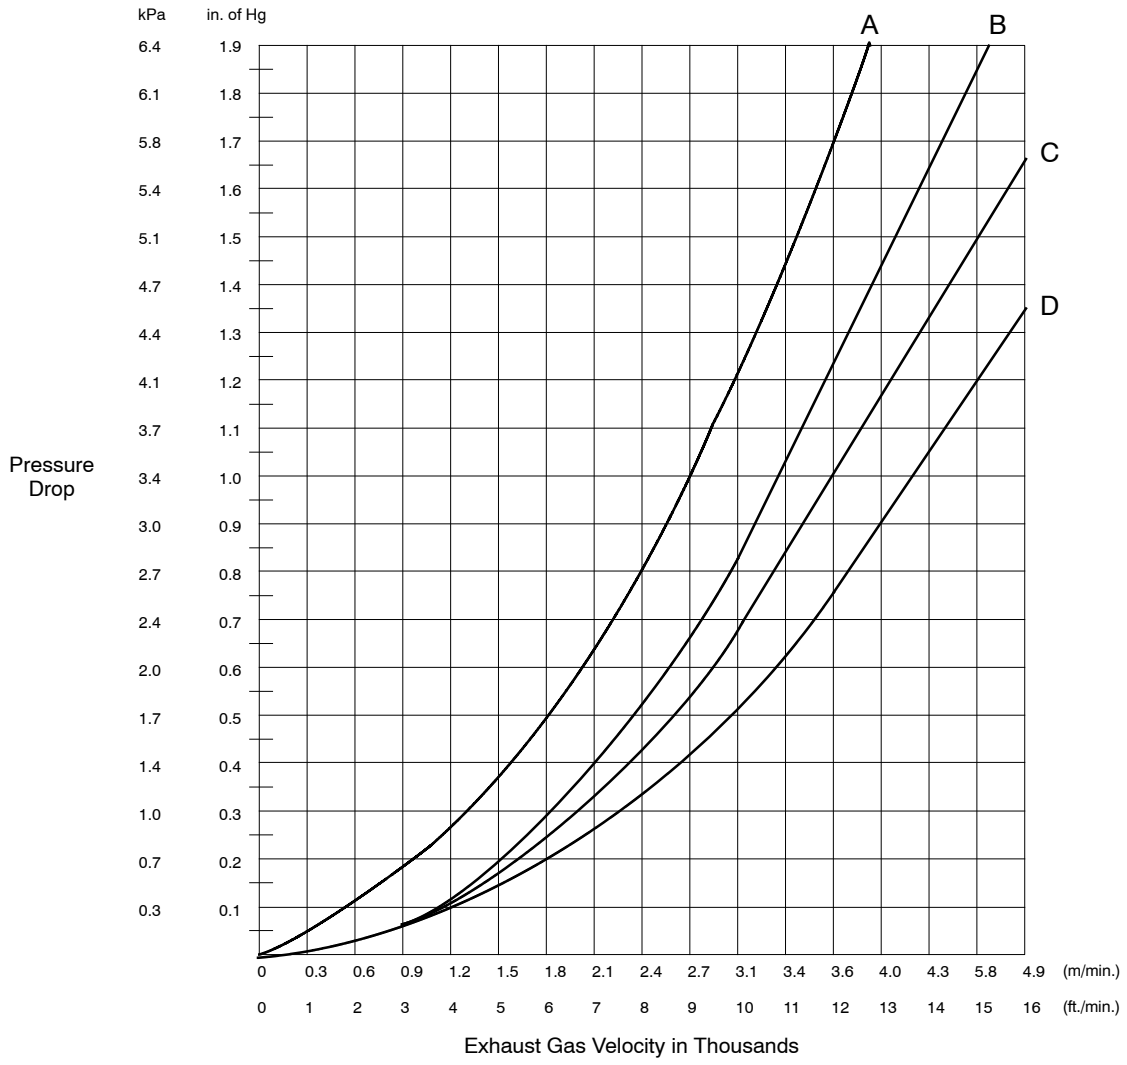
6. Total the number of elbows and flexible sections in the exhaust system between the engine and the exhaust system outlet. Compare the radius of the bend (R) to the pipe diameter where (D) is the nominal pipe diameter in inches. Determine the equivalent length in m (ft.) of straight pipe for the elbows and flexible sections from the following:

Bend Angle	Type	Bend Radius	Conversion Factor
90°	Close	R = D	32 x D* / 12
90°	Medium	R = 2D	10 x D* / 12
90°	Sweep	R = 4D	8 x D* / 12
45°	Close	R = D	15 x D* / 12
45°	Sweep	R = 4D	9 x D* / 12
	Flex Sections		2 x Length† / 12

* Use the diameter of the silencer inlet in *inches* from step 3 for the initial calculation. If the results from step 9 indicate excessive backpressure drop, then recalculate using the larger-diameter pipe size selected.

† Use the flexible exhaust adapter length from step 3 and add any additional flex sections in the exhaust system expressed in *inches*.

Convert the equivalent pipe length calculated in feet to meters using ft. x 0.305 = m, as needed.

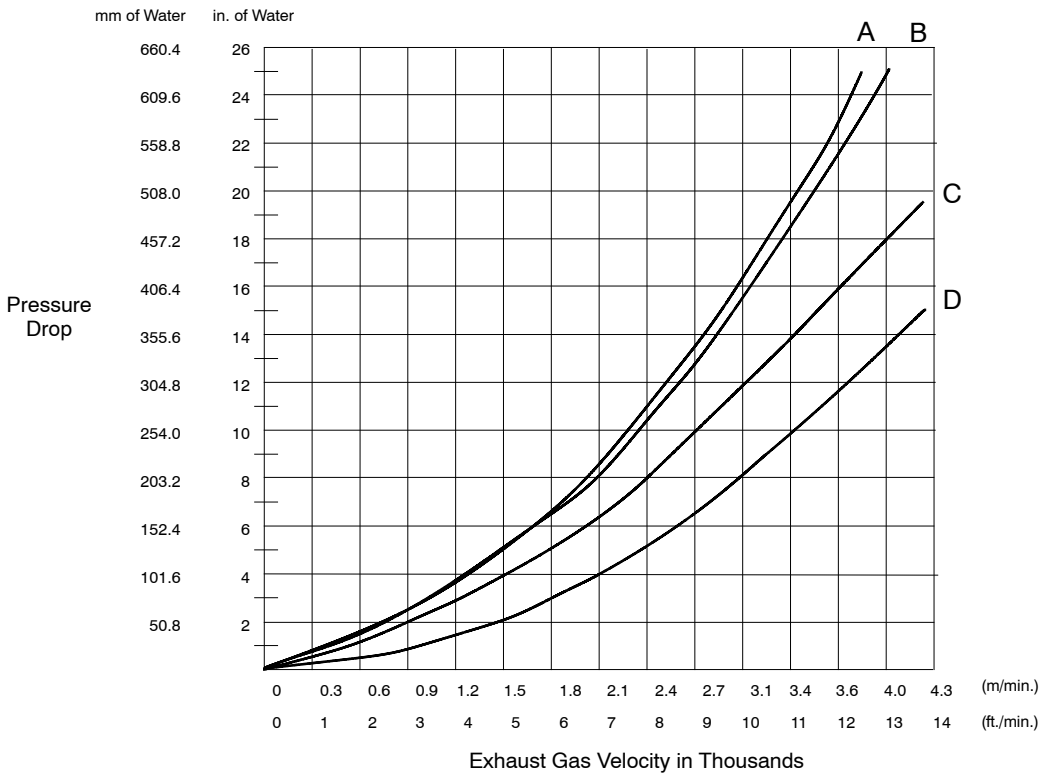


Examples:

45 ° sweep elbows:
9 x 6.0 in. / 12 = 4.5 equiv. ft. or 1.4 equiv. m

90 ° close elbows:
32 x 6.0 in. / 12 = 16.0 equiv. ft. or 4.9 equiv. m

Flexible sections:
2 x 33.75 in. / 12 = 5.6 equiv. ft. or 1.7 equiv. m



Equivalent of straight pipe:
4.5 + 16.0 + 5.6 = 26.1 equiv. straight ft.
1.4 + 4.9 + 1.7 = 8.0 equiv. straight m

A = Hospital Silencer
B = Critical Silencer
C = Residential Silencer
D = Industrial Silencer

Note: When figuring the silencer pressure drop for side inlet, add 0.75 kPa (0.25 in. of mercury or 3.4 in. of water) to the backpressure.

Figure 5-7 Silencer Backpressure Drop (in. of Hg)

A = Hospital Silencer
B = Critical Silencer
C = Residential Silencer
D = Industrial Silencer

Note: When figuring the silencer pressure drop for side inlet, add 0.75 kPa (86 mm of water or 3.4 in. of water) to the backpressure.

Figure 5-8 Silencer Backpressure Drop (in. of water)

7. Determine the total length of straight pipe used in the exhaust system. Add this calculation to the equivalent length for elbows and flexible sections obtained in step 6.

   Example:

   Straight pipe = 3.0 m (10 ft.).
   Equivalent straight pipe from step 6: 8.0 m (26.1 ft.)

   3.0 m + 8.0 m = 11.0 m or
   10 ft. + 26.1 ft. = 36.1 ft. total

8. Refer to Figure 5-9 if the pipe size is 102 mm (4 in.) or less or Figure 5-10 if the pipe size is 127 mm (5 in.) or larger.

   Place a straight edge across the chart with the edge in line with the pipe size in inches (D) on the right column from step 3 and the engine exhaust flow (Q) from step 2 on the left column.

   Read backpressure kPa/m or in. of Hg/ft. (ΔP) from the center column. Calculate the total piping system backpressure by multiplying the total equivalent straight pipe in m (ft.) from step 7 by the kPa/m or in. of Hg/ft. of pipe from this step.

   Example:

   11.0 equiv. m x 0.04 kPa/m =
   0.4 total system backpressure in kPa

   36.1 equiv. ft. x 0.004 in. Hg/ft. =
   0.14 total system backpressure in inches of Hg

9. Add the backpressure of the piping determined in step 8 to the backpressure of the silencer determined in step 5. The total should not exceed the engine manufacturer's maximum allowable system backpressure determined in step 2 or on the generator set's specification sheet. If the total exceeds the maximum, use a larger pipe size or silencer or both. Repeat the calculation if new components are selected to verify that the system backpressure would not exceed the limit using the larger component(s).

   Example:

   0.4 kPa (step 8) + 2.8 kPa (step 5) = 3.2 kPa
   Maximum allowable backpressure = 10.2 kPa
   3.2<10.2 backpressure drop is acceptable

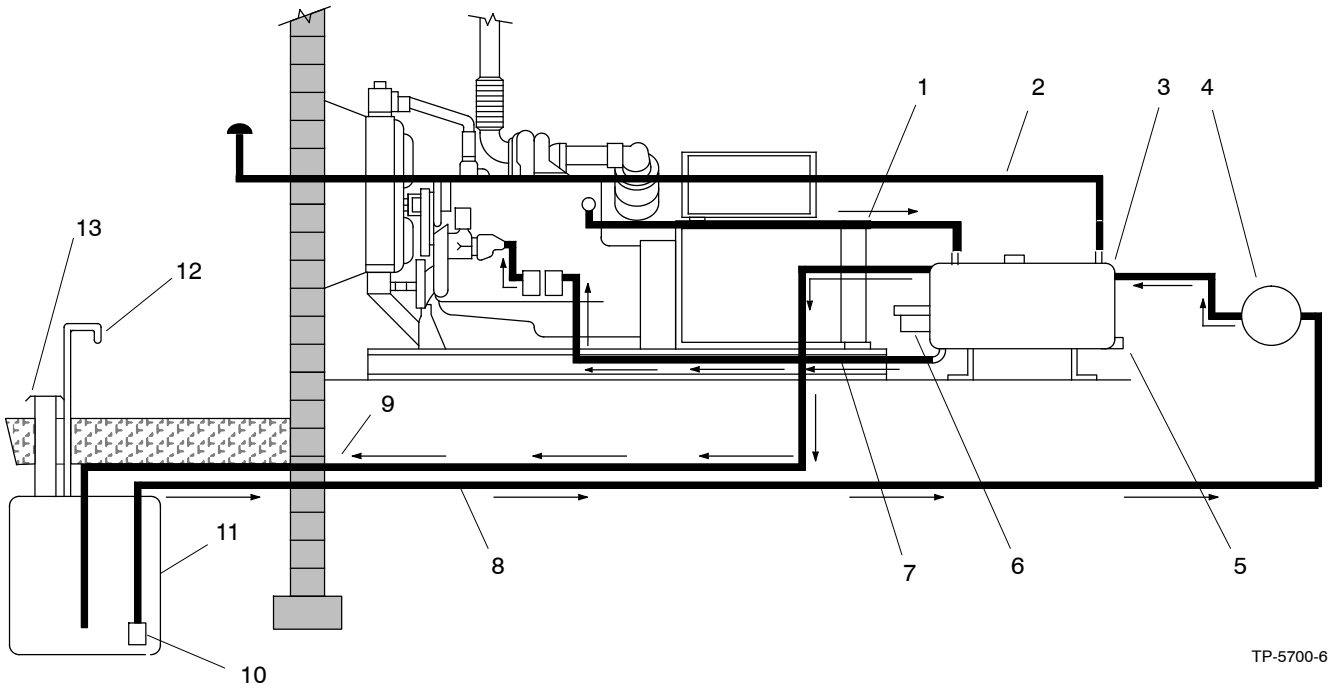
Notes



Comply with applicable state and local codes when installing any fuel system.

6.1 Diesel Fuel Systems

The main components of a typical diesel fuel system are a main fuel storage tank, a day tank, fuel lines, and an auxiliary fuel pump. See Figure 6-1.

6.1.1 Main Tank

Storage. Because it is less volatile than gas or gasoline, diesel fuel is safer to store and handle. Regulations for diesel storage tank placement are less stringent than the regulations for gas or gasoline storage. In some locations, large main tanks are permitted inside the building or enclosure.

Tank location. Locate fuel storage tanks above ground or bury them underground in accordance with applicable codes. Figure 6-2 shows a commonly used above-ground subbase tank contained in the generator set mounting base.

Provide easy access to fuel filters and sediment drains for regular and frequent service. Clean fuel is especially important to diesel engines, which have easily clogged fuel injectors and pumps.

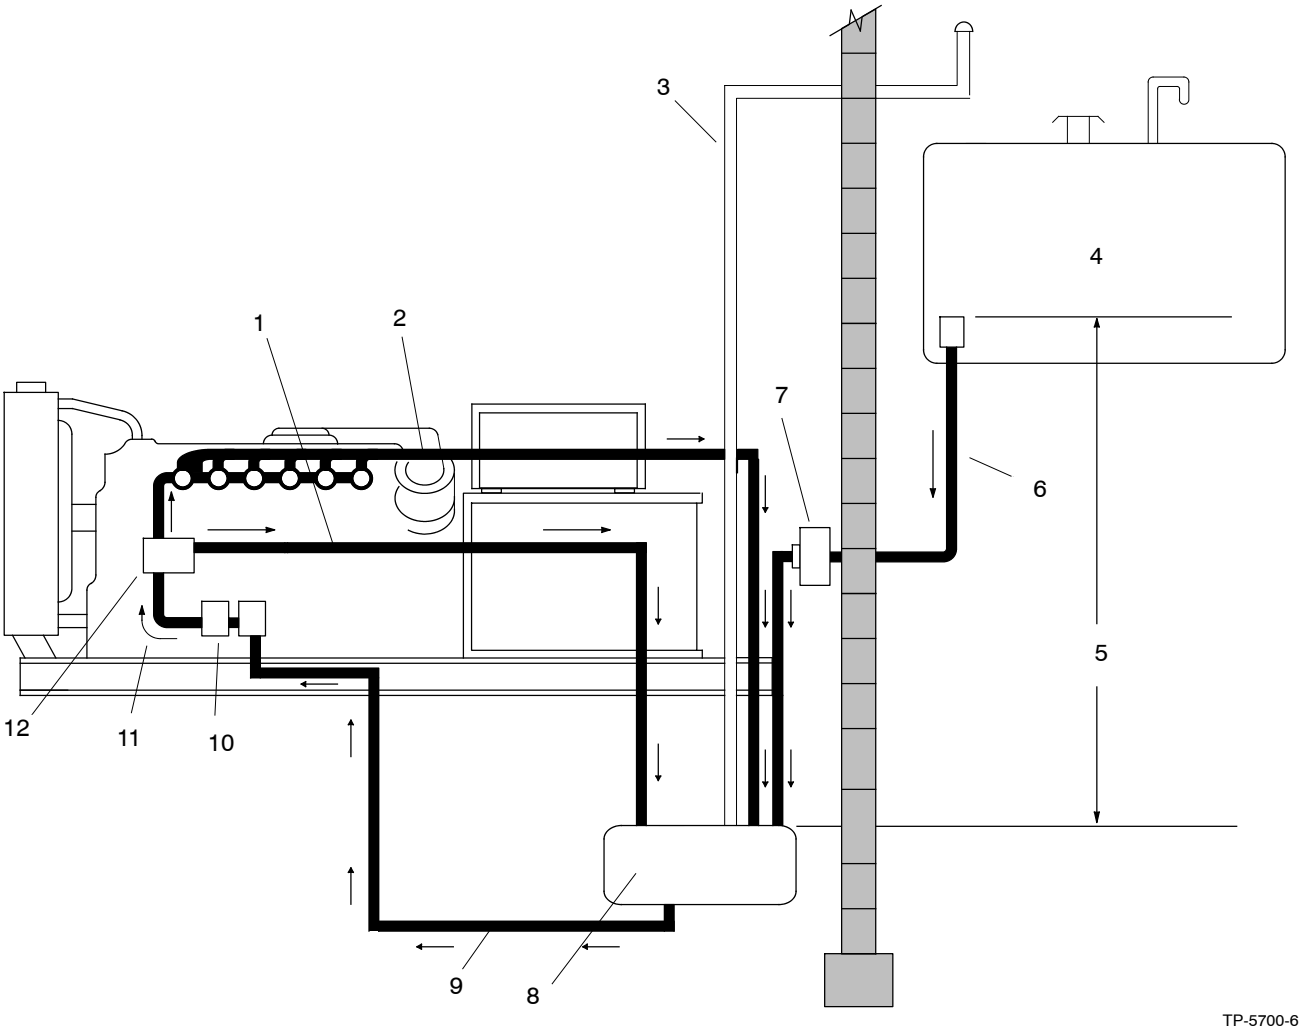
Figure 6-2 Subbase Fuel Tank

Tank size. Codes requiring standby power often specify a minimum onsite fuel supply. Such requirements are included in NFPA 70, National Electrical Code, and NFPA 99, Standard for Health Care Facilities. Diesel fuel deteriorates if stored for more than one year; therefore, size the tank to ensure that regular generator set exercising will use the tank's contents within one year. If there are no applicable code requirements, the manufacturer recommends a tank sized for eight hours of operation at rated load. Refer to the generator set specification sheet for fuel consumption data.

Tank venting. Vent the main fuel tanks to allow air and other gases to escape to the atmosphere without allowing dust, dirt, and moisture to enter the tank.

Fuel expansion. Never fill the tank more than 95% full to allow for fuel expansion. On overhead main tanks, use a fuel shutoff solenoid to prevent hydraulic lock or tank overflow caused by excessive static head fuel pressures.

Fuel alternatives. Most diesel engines operate satisfactorily on No. 2 domestic burner oil available in most parts of the US. If the site heating system is oil-fired, consider supplying the engine with fuel from the same tank used for heating oil to reduce costs and to ensure a continually fresh fuel supply for the engine. This practice necessitates that the fuel oil meets the engine manufacturer's minimum requirements for wax point, pour point, sulfur content, and cetane number as these factors influence cold weather starting and generator set power output. When supplying multiple applications from the same main fuel tank, provide each with a separate supply line.



6.1.2 Day Tanks

The terms *day tank* and *transfer tank* are interchangeable. Having a day tank adjacent to the engine allows the engine fuel transfer pump to easily draw fuel during startup and provides a convenient location to connect fuel injector return lines. See Figure 6-3.

Connect a float-switch-controlled solenoid antisiphon valve or a float valve to prevent siphoning fuel from the main storage tank if the main tank fuel level is above the day tank inlet.

Tank size. Standard tanks are available in sizes from 38–3952 L (10–1044 gal.) with or without integral electric fuel transfer pumps. Because engines are subject to fuel temperature deration above 38°C (100°F) and are subject to damage if operated with fuel temperatures above 60°C (140°F), a day tank providing at least four hours of fuel consumption should be used to provide enough capacity to cool the fuel returning from the engine. If smaller day tanks are used, the generator set manufacturer may recommend installing a fuel cooler or routing engine fuel return lines to the main storage tank. See Figure 6-3.

Optional equipment includes fuel level gauges, manual priming pumps, float switches for pump control, float valves, rupture basins, and low level alarms. Remove the plastic shipping plugs and install metallic pipe plugs in all unused fuel tank ports to provide a liquid-tight seal.

6.1.3 Fuel Lines

The following items describe fuel line selection and application. Never use the fuel piping or fuel line clamps to ground any electrical equipment.

Line type. Use Schedule 40 black-iron pipe, steel tubing, or copper tubing for diesel fuel systems. Diesel fuel reacts adversely with galvanized tanks and piping, producing flaking sediment that quickly clogs filters and causes fuel pump and fuel injector failure. Ensure that any flexible fuel lines used are approved for diesel fuel.

Line size. Use the smallest diameter fuel line that still delivers enough fuel to the engine with an acceptable pressure drop of 6.9 kPa (1.0 psi). Using oversize piping increases the chance of air introduction into the fuel system during engine priming, which increases the potential for fuel pump damage and hard starting.

Flexible connectors. Use flexible connections spanning a minimum of 152 mm (6 in.) between the stationary piping and the engine fuel inlet connection.

Return lines. A diesel system delivers more fuel to the injectors than the engine uses; therefore, a system has one supply line from the fuel tank and at least one return line from the fuel injectors. Size the fuel return lines no smaller than the fuel supply lines.

Route the return fuel line to either the day tank or the main storage tank. Place the return lines as far away from the pickup or fuel diptube as possible to prevent air entry and to keep warm fuel from being reintroduced to the engine. If fuel lines are routed to the day tank, note the day tank size requirements in Section 6.1.2, Day Tanks.

A properly designed fuel return line is unrestricted and as short as possible, and it allows gravity return of fuel to the storage tanks. In installations where gravity return is not possible, obtain approval of the design from the generator set supplier based upon the engine's specifications before installing a fuel system with static head pressure on the return lines. Fuel return line restriction can cause engine hydraulic lock or uncontrollable overspeed on some systems.

6.1.4 Auxiliary Fuel Pumps

Primary, engine-driven fuel pumps typically develop a maximum of 48 kPa (7 psi) pressure and draw fuel to approximately 1.2–1.4 m (4–5 ft.) vertically or 6 m (20 ft.) horizontally. When the main tank is located a greater distance from the engine or for a more reliable fuel system, use an auxiliary pump alone or in connection with a day tank. See Figure 6-3. Limit auxiliary fuel pump pressure to approximately 35 kPa (5 psi).

Use a shutoff solenoid valve wired into the engine run circuit or a check valve to help keep the fuel line primed. Install the check valve on the outlet side of the auxiliary fuel pump to minimize inlet restriction.

Auxiliary fuel pump options. On engines using less than 38 L (10 gal.) of fuel per hour (approximately 100 kW or less), connect an engine starting battery-powered electric fuel transfer pump in series with the engine-driven transfer pump. Locate the electric pump nearer to the fuel tank than to the engine. An auxiliary pump located at the fuel tank approximately doubles the horizontal and vertical distance limits of a single engine-driven pump.

On engines using more than 38 L (10 gal.) of fuel per hour or when drawing fuel more than 1.8 m (6 ft.) vertically or 12 m (40 ft.) horizontally, use an electric motor-driven positive displacement pump with a day tank and float switch. Electrically connect the fuel pump to the transfer switch load side for maximum reliability. This type of pump can typically lift fuel 5.5 m (18 ft.) or draw it horizontally up to 61 m (200 ft.).

Where vertical runs exceed 5.5 m (18 ft.) or horizontal runs exceed 61 m (200 ft.), remote-mount the pump adjacent to the fuel storage tank. This type of installation allows these pumps to push fuel over 305 m (1000 ft.) horizontally or more than 31 m (100 ft.) vertically and deliver adequate fuel for generator sets up to 2000 kW. Always connect a positive-displacement pump directly to a day tank and float switch to protect the engine fuel system from excessive fuel pressures.

6.2 Gas Fuel Systems, Common Components

Gas fuel systems operate on either LP (liquefied petroleum) or natural gas.

Note: Design and install gas fuel systems in accordance with NFPA 54, National Fuel Gas Code, and applicable local codes.

All gas systems include a carburetor, secondary gas regulator, electric gas fuel solenoid shutoff valve, and flexible fuel connector.

6.2.1 Gas Lines

Never use fuel piping to ground electrical equipment. The gas supplier is responsible for installation, repair, and alteration to gas piping.

Line type. Use Schedule 40 black-iron pipe for gas piping. Copper tubing may be used if the fuel does not contain hydrogen sulfide or other ingredients that react chemically with copper.

Line size. Size piping according to the requirements of the equipment. Refer to the generator set specification sheet or the dimension drawing for detailed information on your system. In addition to the actual fuel consumption, consider the following pressure loss factors:

- Pipe length
- Other appliances on the same fuel supply
- Number of fittings

Flexible connections. Rigid-mount the piping but protect it from vibration. Use flexible connections spanning a minimum of 152 mm (6 in.) between the stationary piping and the engine fuel inlet connection.

6.2.2 Gas Regulators

Gas regulators reduce high incoming fuel pressures to lower levels acceptable for engines. Refer to the generator set spec sheet for fuel supply pressures. Install a solenoid valve upstream from the gas regulator and the flexible fuel connector to prevent the accumulation of an explosive mixture of gas and air caused by leaks in the flexible connection or the gas regulator. The generator set installer normally wires the engine battery-powered solenoid valve to the engine starting controls to open the valve when the engine cranks or runs.

For UL compliance, the fuel solenoid valves are needed per UL 2200, Section 35.3.2.2.1.

The typical gas system uses two gas regulators:

- **Primary gas regulator.** Provides initial control of gas from the fuel supply. The primary gas regulator reduces the high pressure from a tank or transmission line to the low pressure required by the secondary gas regulator(s). Typically, the primary gas regulator is set at the higher pressure value when a range is given. The gas supplier typically provides the primary gas regulator, as conditions that dictate the type of gas regulator used vary depending on the method of supplying fuel. The supplier is also responsible for providing sufficient gas pressure to operate the primary gas regulator. Primary gas regulator must be vented to the outside if installed within any building.

- **Secondary gas regulator.** This low-pressure gas regulator is mounted on the engine and limits the maximum inlet pressure to the engine. The engine operates satisfactorily at the lower pressure value when a range is given, but these lower pressures may result in poor response to load changes or a lack of power if the primary gas regulator is not near the engine.

Modification for fuel type. Many gas regulators are compatible with both natural gas and LP gas. Typically, the user installs the spring and retainer in the gas regulator when connecting to natural gas and removes it from the gas regulator when connecting to LP vapor gas. Refer to the appropriate generator set's operation manual and/or the decal attached to the generator set for information regarding spring/adjustment screw usage for specific models. Some models may require new diaphragm kits and/or inverting the gas regulator when changing fuel type.

Rating change. Converting the fuel will change the generator set rating. See the generator set specification sheet for ratings with natural gas and LP. Order a new nameplate with the updated rating and fuel information from an authorized distributor/dealer, if necessary. Provide the following information from the original nameplate:

- Model number
- Spec number
- Serial number
- Fuel (original and new)
- kW
- kVA
- Amps
- Volts
- Hz

Attach the new nameplate over the old one. Do NOT cover the UL listing information on the old nameplate.

Installation position for fuel type. The gas regulator functions normally pointing downward for both natural gas and LP gas. If only natural gas fuel is used, the gas regulator should be installed pointing upward.

Pressure testing. Some gas regulators provide for installation of a pressure gauge to test inlet and outlet pressures. If no such provision is available, install pipe tees in the fuel line to test pressure and use pipe plugs to plug unused openings.

6.3 LP Fuel Systems

Fuel characteristics. LP fuel exists as a vapor and a liquid in pressurized tanks. Since LP fuel does not deteriorate in storage, a large supply of fuel can be kept onsite indefinitely for operation during emergency conditions. This makes LP gas ideal for applications with uninterrupted (onsite) fuel supply requirements.

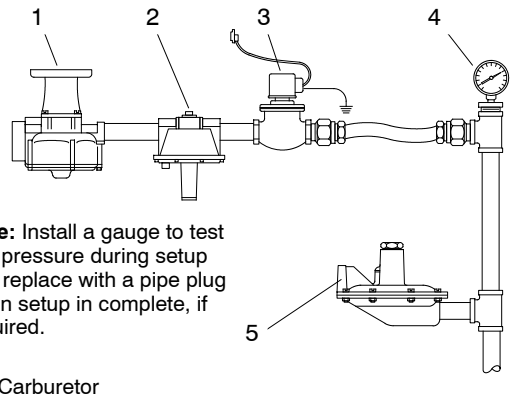
Fuel mixture. LP gas is propane, butane, or a mixture of the two gases. The ratio of butane to propane is especially important when the fuel flows from a large outdoor tank. A fuel supplier may fill the tank in the warm summer months with a mixture composed mainly of butane; however, this mixture may not provide sufficient vaporized pressure at cold temperatures to start and operate the engine. A local fuel supplier is likely to be the best source of information on what size tank is necessary to provide adequate fuel vapor.

The fuel mixture and vaporization pressure at the anticipated temperatures influence the selection of gas regulator equipment. Pure butane gas has little or no vaporization pressure in temperatures below 4°C (40°F). Even at 21°C (70°F), the pressure is approximately 124 kPa (18 psi). Some primary gas regulators do not operate at tank pressures below 207 kPa (30 psi) while others operate at incoming pressures as low as 20.7–34.5 kPa (3–5 psi).

Fuel consumption and tank size. Since LP fuel is supplied in pressurized tanks in liquid form, it must be converted to a vapor state before being introduced into the carburetor. The amount of vapor contained in 3.8 L (1.0 gal.) of liquid (LP) fuel is:

Butane Gas	0.88 m^3 (31.26 cu. ft.)
Propane Gas	1.03 m^3 (36.39 cu. ft.)

See the generator set specification sheets for fuel consumption at different loads, and contact your fuel supplier for information regarding tank sizes.



System types. Single-source gas fuel systems include LP gas vapor-withdrawal and LP gas liquid-withdrawal.

6.3.1 LP Gas Vapor-Withdrawal Systems

A vapor-withdrawal system draws on the fuel vapor that collects in the space above the liquid fuel. Consider the following during installation:

- Generally, allow 10%–20% of tank capacity for fuel expansion from a liquid to a vapor state. The liquid level in LP gas tanks must never exceed 90% of the tank capacity.
- Maintain air temperature surrounding the tank high enough to vaporize the liquid fuel.

Applications in colder climates may require an independent heat source to increase natural vaporization within the tank. Withdraw liquid fuel and vaporize it in an electrically heated, engine water jacket-heated, or LP gas-heated vaporizer. Figure 6-4 shows the components of the vapor-withdrawal system used in a typical stationary application. The LP gas regulator is typically installed in the inverted position (pointing downward).

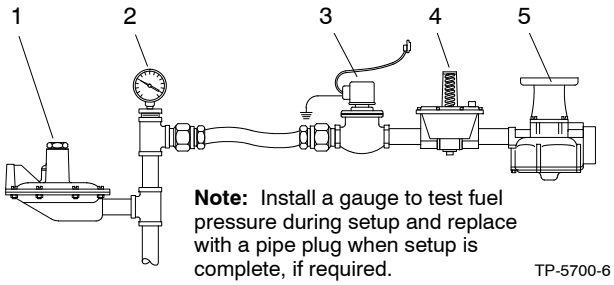
2. Secondary gas regulator
3. Solenoid valve (quantity of two in series may be required for UL applications)
4. Pressure gauge
5. Primary gas regulator (supplied by gas supplier or installer)

Figure 6-4 Typical LP Gas Vapor-Withdrawal System

6.3.2 LP Gas Liquid-Withdrawal Systems

LP liquid-withdrawal fuel systems are available for generator sets but are not recommended for automatic standby service. With liquid-withdrawal systems, liquid LP at 1034–1379 kPa (150–200 psi) flows to the engine. A combination of converters (vaporizers) and gas regulators then reduces the pressure to a usable level.

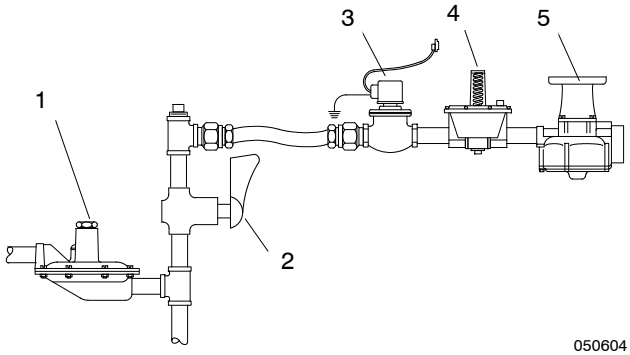
In Figure 6-5, a converter (a combination of a vaporizer and primary and secondary gas regulators) changes the liquid to vapor using heat from the engine's cooling system. For a period following startup, a liquid-withdrawal system may be unable to vaporize enough fuel for an engine running under load until the engine reaches operating temperature. The engine needs time to warm sufficiently to provide adequate heat to vaporize the fuel.



1. Carburetor
2. Converter (vaporizer)
3. Solenoid valve (quantity of two in series may be required for UL applications)
4. LP gas filter (supplied by gas supplier or installer)

Figure 6-5 LP Gas Liquid Withdrawal System

Some codes prohibit gas fuel pressurization greater than 34.5 kPa (5 psi) inside buildings. This might preclude the use of a liquid-withdrawal system. To ensure code compliance, converters are sometimes located outside the building housing the generator set. However, the great length of pipe between the converter and the carburetor does not allow sufficient heat buildup and heat retention to maintain the fuel in its vapor state, which can cause startup problems.



6.4 Natural Gas Systems

The utility supplies natural gas in a vapor state. A natural gas fuel system consists of the same basic components and operates with the same general sequence as LP gas vapor-withdrawal systems. See Figure 6-6 and Figure 6-7. Note that when the heat content of the fuel falls below 1000 Btu, as it does with sewage-derived and some other natural gas fuels, the generator set will not produce its rated power. The natural gas regulator is typically installed in the upright position (pointing upward).

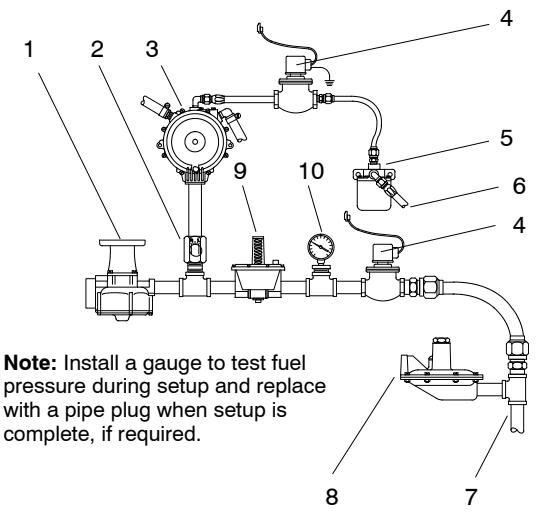
6.5 Combination Systems

Combination fuel source systems include:



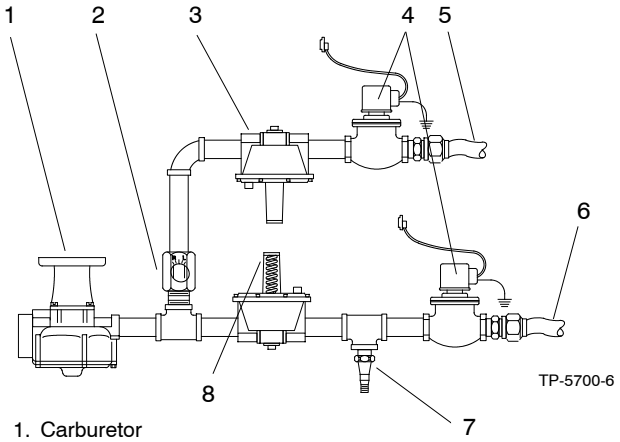
- Natural gas and LP gas

6.5.1 Combination Natural Gas and LP Gas

Some applications use natural gas as the main fuel and LP gas as the emergency fuel when natural gas is not available.

The natural gas and *LP gas, liquid withdrawal* system uses a converter (vaporizer) to change the LP liquid to gas vapor. A pressure switch on the primary fuel source closes when fuel pressure drops, which energizes a relay that closes the primary fuel solenoid and opens the secondary or emergency fuel solenoid.

A separate LP gas load adjustment valve ensures the right fuel-to-air mixture in the carburetor. The load adjustment valve is located inline between the converter (vaporizer) and the carburetor. See Figure 6-8.



Note: Install a gauge to test fuel pressure during setup and replace with a pipe plug when setup is complete, if required.

Figure 6-8 Natural Gas and LP Gas System, Liquid Withdrawal

The natural gas and *LP gas, vapor withdrawal* system contains a separate secondary gas regulator and solenoid valve for each fuel. The LP gas regulator typically mounts in the inverted position. A pressure switch on the primary fuel source closes when fuel pressure drops, which energizes a relay that closes the primary fuel solenoid and opens the secondary or emergency fuel solenoid. A separate LP gas load adjustment valve ensures the right fuel-to-air mixture in the carburetor.

The load adjustment valve is located inline between the secondary gas regulator and the carburetor. See Figure 6-9.

6.6 Pipe Size Requirements for Gas Fuel Systems

The type of fuel, the distance it must travel from gas meter/tank to fuel shutoff solenoid, and the amount consumed by the engine must be considered when determining fuel line pipe size.

To find the correction necessary for the different specific gravity of the particular fuel used, refer to Figure 6-10.

Figure 6-11 is based on gas pressures of 3.4 kPa (0.5 psi, 13.8 in. water column) or less and a pressure drop of 0.12 kPa (0.018 psi, 0.5 in. water column) with a 0.60 specific gravity and with a normal amount of restriction from fittings. To calculate the correct pipe size for a specific installation, refer to the chart and follow the procedure outlined below.

Fuel	Specific Gravity	Correction Factor
Sewage Gas	0.55	1.040
Natural Gas	0.65	0.962
Air	1.00	0.775
Propane (LP)	1.50	0.633
Butane	2.10	0.535

Note: When the fuel has a specific gravity of 0.7 or less no correction factor is necessary—use this table without a correction factor.

Figure 6-11 Maximum Flow Capacity of Pipe in Cubic Meters (Cubic Feet) of Gas per Hour

1. Refer to the fuel consumption on the generator set specification sheet. Note type of fuel used, generator set application rating, and the m^3/hr. (ft^3/hr.) consumption at 100% load.

   Example:
   80 kW, propane gas, 60 Hz standby rating = 12.0 m^3/hr. (425 ft^3/hr.).

2. Refer to the Fuel Correction Factors in Figure 6-10. Locate the correction factor for specific gravity of the selected fuel.

   When the fuel has a specific gravity of 0.7 or less no correction factor is necessary—use Figure 6-11 without a correction factor.

   Example:
   propane gas specific gravity = 1.50
   fuel correction factor = 0.633.

3. Divide the consumption value from step 1 by the correction factor from step 2.

   Example:
   12.0 m^3/hr. (425 ft^3/hr.) divided by 0.633 = 19.0 m^3/hr. (671 ft^3/hr.).

4. Determine the length of pipe between the gas meter/tank and the fuel shutoff solenoid at the generator set.

   Example:
   34.7 m (114 ft.).

5. Find the value closest to pipe length in the Length of Pipe column in Figure 6-11.

   Example:
   38.1 m (125 ft.).

   Example:
   At 28.9 m^3/hr. (1020 ft^3/hr.) the pipe size = 2 in. IPS.

6. Move vertically down the table in Figure 6-11 from the determined value in Length of Pipe column.

   Example:
   38.1 m (125 ft.)

   Stop at the value that is equal to or greater than corrected consumption value from step 3.

   Example:
   28.9m^3/hr. (1020 ft.^{3}/hr.).

7. Move to the left column from the value in step 6 to determine the correct pipe size.

Before installing the generator set, provide for electrical connections through conduit to the transfer switch and other accessories for the generator set. Carefully install the selected generator set accessories. Route wiring to the generator set through flexible connections. Regarding the application of bushings and grommets for the entry of wiring, use Class 1 wiring methods for field wiring connections to a Class 2 circuit. Comply with applicable national and local codes when installing a wiring system.

AC circuit protection. All AC circuits must include circuit breaker or fuse protection. Select a circuit breaker for up to 125% of the rated generator set output current. The circuit breaker must open all ungrounded conductors. The circuit breaker or fuse must be mounted within 7.6 m (25 ft.) of the alternator output terminals.

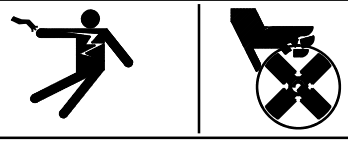
⚠ WARNING

Accidental starting.
Can cause severe injury or death.

Disconnect the battery cables before working on the generator set. Remove the negative (-) lead first when disconnecting the battery. Reconnect the negative (-) lead last when reconnecting the battery.

Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) Move the generator set master switch to the OFF position. (2) Disconnect the power to the battery charger. (3) Remove the battery cables, negative (-) lead first. Reconnect the negative (-) lead last when reconnecting the battery. Follow these precautions to prevent starting of the generator set by an automatic transfer switch, remote start/stop switch, or engine start command from a remote computer.

(Decision-Maker® 3+ and 550 Controllers)



Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) Press the generator set off/reset button to shut down the generator set. (2) Disconnect the power to the battery charger, if equipped. (3) Remove the battery cables, negative (-) lead first. Reconnect the negative (-) lead last when reconnecting the battery. Follow these precautions to prevent the starting of the generator set by the remote start/stop switch.

(Decision-Maker® 3000, 3500, and 6000 Controllers)

Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) If the controller is not already in the MAN (manual) mode, press the Controller Mode button and then press the MAN mode button. (2) If the generator set is running, press and hold the Manual-Stop button for at least 2 seconds to stop the generator set. (3) Press the Controller Mode button and then press the controller Off mode button. (4) Disconnect the power to the battery charger, if equipped. (5) Remove the battery cables, negative (-) lead first. Reconnect the negative (-) lead last when reconnecting the battery. Follow these precautions to prevent the starting of the generator set by the remote start/stop switch.

(Decision-Maker® 8000 Controller)

⚠ WARNING

Hazardous voltage. Moving parts.
Can cause severe injury or death.

Operate the generator set only when all guards and electrical enclosures are in place.

Short circuits. Hazardous voltage/current can cause severe injury or death. Short circuits can cause bodily injury and/or equipment damage**.** Do not contact electrical connections with tools or jewelry while making adjustments or repairs. Remove all jewelry before servicing the equipment.

7.1 Generator Set Voltage Reconnection

To change the voltage of 10- or 12-lead generator sets, *use the procedure shown in the operation manual containing the respective controller setup.* Adjust the governor and voltage regulator for frequency changes. Consult the generator set service manual for frequency adjustment information.

Voltage reconnection. Affix a notice to the generator set after reconnecting the set to a voltage different from the voltage on the nameplate. Order voltage reconnection decal 246242 from an authorized service distributor/ dealer.

Equipment damage. Verify that the voltage ratings of the transfer switch, line circuit breakers, and other accessories match the selected line voltage.

Reconnect the generator set stator leads to change the output phase or voltage. Reference the appropriate voltage reconnection drawing in the respective Wiring Diagram Manual..

Follow the safety precautions at the front of this manual and in the text and observe National Electrical Code (NEC) guidelines.

7.2 Electrical Connections

Several electrical connections must be made between the generator set and other components of the system for proper operation. Because of the large number of accessories and possible combinations, this manual does not address specific applications. Refer to the submittal catalog accessory drawings and wiring diagrams for connection and location. Most field-installed accessory kits include installation instructions.

For customer-supplied wiring, select the wire temperature rating in Figure 7-1 based upon the following criteria:

- Select row 1, 2, 3, or 4 if the circuit rating is 110 amperes or less or requires #1 AWG (42.4 mm^2) or smaller conductors.
- Select row 3 or 4 if the circuit rating is greater than 110 amperes or requires #1 AWG (42.4 mm^2) or larger conductors.

Comply with applicable national and local codes when installing a wiring system.

Row	Temp. Rating	Copper (Cu) Only	Cu/Aluminum (Al) Combinations	Al Only
1	60°C (140°F) or 75°C (167°F)	Use No. * AWG, 60°C wire or use No. * AWG, 75°C wire	Use 60°C wire, either No. * AWG Cu, or No. * AWG Al or use 75°C wire, either No. * AWG Cu or No. * AWG Al	Use 60°C wire, No. * AWG or use 75°C wire, No. * AWG
2	60°C (140°F)	Use No. * AWG, 60°C wire	Use 60°C wire, either No. * AWG Cu or No. * AWG Al	Use 60°C wire, No. * AWG
3	75°C (167°F)	Use No. *† AWG, 75°C wire	Use 75°C wire, either No. *† AWG Cu or No. *† AWG Al	Use 75°C wire, No.*† AWG
4	90°C (194°F)	Use No. *† AWG, 90°C wire	Use 90°C wire, either No. *† AWG Cu or No. *† AWG Al	Use 90°C wire, No.*† AWG

* The wire size for 60°C (140°F) wire is not required to be included in the marking. If included, the wire size is based on ampacities for the wire given in Table 310-16 of the National Electrical Code®, in ANSI/NFPA 70, and on 115% of the maximum current that the circuit carries under rated conditions. The National Electrical Code® is a registered trademark of the National Fire Protection Association, Inc.

† Use the larger of the following conductors: the same size conductor as that used for the temperature test or one selected using the guidelines in the preceding footnote.

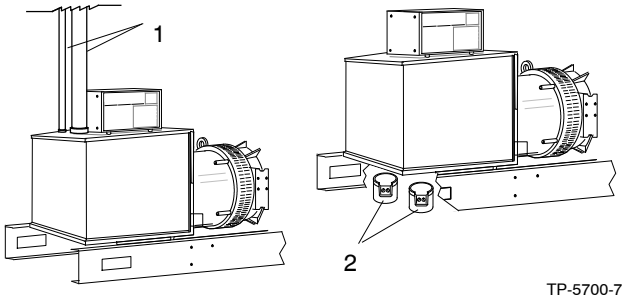


Figure 7-1 Terminal Markings for Various Temperature Ratings and Conductors

7.3 Load Lead Connections

Feed load leads to the generator junction box from one of several different areas. Generator sets rated 300 kW and below commonly use the bottom entry where conduit is stubbed up into the junction box from the concrete slab. Other methods include flexible conduit roughed into the sides or top of the junction box. When using flexible conduit, do not block the front or rear of the controller. See Figure 7-2.

Use a minimum of 13 mm (0.5 in.) spacing between the conduit bushing and any uninsulated live parts in the junction box. All conduit openings in the junction box must be made such that no metal particles including drill chips contaminate the components in the junction box.

Generator sets larger than 300 kW have the junction box mounted on the rear of the generator set. Larger sets may have oversized junction boxes supplied as an option or to accommodate bus bar connections. Refer to the generator set dimension drawing and/or the electrical contractor prints for detailed information including stub-up area recommendations.

Figure 7-2 Typical Load Lead Connection

The four bus bars contained in the optional bus bar kits simplify the connection process by offering a neutral bus bar in addition to the three load bars. Optional bus lugs offer an array of terminal and wire connections.

7.4 Grounding and Grounded Conductor (Neutral) Connections

Connect the electrical system grounding conductor to the equipment grounding connector on the alternator. See Figure 7-3. Depending upon code requirements, the grounded conductor (neutral) connection is typically grounded.

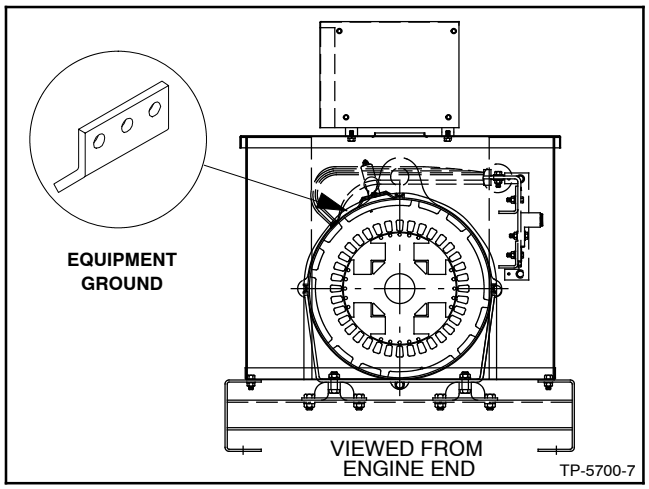

Figure 7-3 Generator Set Equipment Grounding Connection

Ungrounded neutral connections use an insulated standoff (not supplied) to isolate the neutral connection from the grounding connection. For grounding lug selection, see Figure 7-4.

The four bus bars contained in the optional bus bar kits simplify the connection process by offering a neutral bus bar in addition to the three load bars. Optional bus lugs offer an array of terminal and wire connections.

Generator sets are typically shipped from the factory with the neutral attached to the alternator in the junction box for safety reasons per NFPA 70. At installation, the neutral can remain grounded at the alternator or be lifted from the grounding stud and isolated if the installation requires an ungrounded neutral connection at the generator set. The generator set will operate properly in either configuration.

Various regulations and site configurations including the National Electrical Code® (NEC), local codes, and the type of transfer switch used in the application determine the grounding of the neutral at the generator set.

7.5 Terminal Connector Torque

Use torque values shown in Figure 7-5 or Figure 7-6 for terminal connectors. Refer to UL 486A–486B and UL 486E for information on terminal connectors for aluminum and/or copper conductors. See Section 7.2, Electrical Connections, for information on temperature rating of the customer-supplied wire. Comply with applicable national and local codes when installing a wiring system.

If a connector has a clamp screw such as a slotted, hexagonal head screw with more than one means of tightening, test the connector using both applicable torque values provided in Figure 7-6.

7.6 Batteries

Battery location. When determining the battery placement, ensure that the location:

- Is clean, dry, and not exposed to extreme temperatures
- Provides easy access to battery caps for checking the electrolyte level (when using maintenance type batteries)
- Is close to the generator set to keep cables short, ensuring maximum output

Refer to the submittal drawings for the generator set when choosing a battery rack. Figure 7-7 shows a typical battery system.

1. Battery cables
2. Battery secured in mounting rack
3. End view
4. Generator set skid

Figure 7-7 Typical Battery System, Side View

Battery type. Starting batteries are usually the lead-acid type and are sized according to the engine manufacturer's recommendation for a particular ambient temperature and required cranking time. NFPA 110 recommends cranking periods, including a single 45-second cycle for generator sets below 15 kW and three 15-second crank cycles separated by 15-second rests for larger models. Refer to the respective generator set specification sheet for the required battery cold-cranking ampere (CCA) rating.

Nickel-cadmium batteries are sometimes used for standby generator sets because of their long life (20 years). However, initial high cost, larger space requirements, and special charging requirements can offset this benefit. Therefore, conventional lead-acid batteries have proven satisfactory for the majority of generator set applications.

Battery cables. A UL 2200 listed generator set requires battery cables with positive (+) lead boots. Factory-supplied and optional battery cables include positive (+) lead boots. When battery cables are not factory-supplied, source battery cables with positive (+) lead boots for UL 2200 compliance.

Note: Some units are equipped with an insulating and reflective heat shield sleeve on the battery cables and other wires that are fastened to the starter solenoid. This sleeve is a conductive material and must be secured approximately 25 mm (1 in.) away from the exposed cable terminal.

7.7 Battery Chargers

Most industrial generator sets use an engine-driven, battery-charging alternator to charge the batteries whenever the generator set operates. Engine-driven systems are normally capable of charge rates of 30 amps or more and can quickly restore the charge used in a normal cranking cycle. When the engine is not operating, a very low charge rate from an AC-powered battery charger is usually sufficient to maintain a full charge on the batteries.

Some industrial generator sets have no battery-charging alternator and, therefore, require a separate AC- powered battery charger.

Select an automatic or manual battery charger with a high charge rate of 2 amps and a trickle charge rate up to 300 milliamps. The low maximum charge rate makes the charger ill-suited to restore fully discharged batteries. For full recovery capability independent of the engine-driven charging system, use an automatic float battery charger with a high charge rate of at least 10 amps.

Use separate, self-contained battery chargers or units built into the automatic transfer switch. Run leads from a transfer switch-mounted battery charger in conduit separate from the conduit that holds the generator load cables or remote engine-start circuits.

Note: Digital controllers with microprocessor circuitry and vacuum fluorescent displays typically draw more than 300 milliamps, making trickle charge battery chargers inappropriate for systems with these controllers. Select only automatic float/equalize battery chargers with a 3 amp or greater rating for units with digital controllers.

Battery failure is the most common reason for emergency generator set start failure. Two common battery failure causes are a manual charge rate set too low to maintain the battery and a manual charge rate set too high, resulting in loss of battery electrolyte. To avoid battery failure, use an automatic float charger, which varies the charge rate in response to battery condition.

For large engines with two starters, use either one bank of batteries and chargers for both starters or use separate battery systems. The latter system is preferable because it reduces the chance of a single component failure rendering the entire system inoperative.

7.8 Component and Accessory Power Source Requirements

Several components require a power source other than the engine starting batteries. The utility power supply outlet or electrical box should be in close proximity to the generator set. Some factory-supplied enclosures are available with electrical hook-up connections. Most accessories require a dedicated circuit with separate circuit breaker. Comply with applicable national and local codes when providing an electrical power source connection. These items include but are not limited to the following items:

- **Alternator Strip Heater** requires a 110–120 volt or 190–240 volt, 50/60 Hz, 15-amp power source. Check the component and instructions for specific information.
- **Battery Charger** typically requires a 110–120 volt or 190–240 volt, 50/60 Hz power source. Some generator set models require multiple battery chargers. Check the component for specific information as some battery chargers are only 110–120 volt, 50/60 Hz. See Section 7.7 Battery Chargers for additional information.
- **Battery Heater** requires a 110–120 volt, 50/60 Hz, 15-amp power source. Some kits require multiple outlets for the plate and wrap connections. Check the component and instructions for specific information.
- **Controller Heater (APM802 Controller only)** requires a 220–240 volt, 50/60 Hz power source. Check the component and instructions for specific information.
- **Crankcase Ventilation Heater (Some 125/150 kW Gas Models only)** require a 110–120 volt, 50/60 Hz, 37.5 watt power source. Check the component and instructions for specific information.
- **Engine Block Heater** typically requires a 110–120 or 190–240 volt, 50/60 Hz, 15- or 20-amp power source. Some kits require multiple outlet circuits. Check the component and instructions for specific information. See Section 4.8 Block Heaters for additional information.

7.9 Optional Accessories

The generator set manufacturer offers optional accessories that require connection to other components in the system. These accessories enable the generator set to meet standards for local and national codes, make operation and service more convenient, or satisfy specific customer installation requirements.

Accessories vary with each generator set model and controller. Accessories are available factory-installed and/or shipped loose. See Figure 7-8 for a list of available kits. Some accessories are available only with the microprocessor and digital controllers. Obtain the most current list of accessories from the respective generator set specification sheet or by contacting your local authorized service distributor/ dealer.

Accessory kits generally include installation instructions. See the wiring diagrams manual for electrical connections not shown in this section. See the installation instructions and drawings supplied with the kit for information on the kit mounting location.

The instructions provided with the accessory kit supersede these instructions, if different. In general, run AC and DC wiring in separate conduit. Use shielded cable for all analog inputs. Observe all applicable national and local electrical codes during accessory installation.

Accessory wiring. To determine the appropriate size for the customer-supplied wiring of the engine battery-powered accessories, use the guidelines in Figure 7-10. Use 18–20 gauge wire for *signal wires* up to 305 m (1000 ft.).

Length, m (ft.)	Wire Gauge
30.5 (100)	18–20
152.4 (500)	14
304.8 (1000)	10

Figure 7-10 Wire Length and Size, Lead N and 42B

Match the wire terminals to the terminal strip conductor screw size. Use a maximum of two wire terminals per terminal strip screw unless otherwise noted on the respective accessory drawing or installation instruction.

Accessory connections. Do not direct-connect accessories to the controller terminal strip. Connect accessories to either a single-relay dry contact kit or ten-relay dry contact kit. Connect the dry contact kit(s) to the controller (customer) connection kit. Connect all accessories except the emergency stop kit to the connection kit terminal strip(s).

Terminal strips and available connections vary by controller. Refer to the respective controller operation manual and the accessory wiring diagrams in the wiring diagram manual for connection of kits. Field-installed accessories include installation instructions and/or wiring diagrams.

7.9.1 Bus Bar Kits/Bus Lugs

The four bus bars contained in the optional bus bar kits simplify the connection process by offering a neutral bus bar in addition to the three load bars. Optional bus lugs offer an array of terminal and wire connections. See Figure 7-11.

7.9.2 Gas Fuel Valve Kit

This section provides the wiring information for an *additional* gas fuel valve kit required for UL Approval. See Figure 7-12. Refer to the respective generator set wiring diagrams for additional information and for LP liquid applications.

7.9.3 Line Circuit Breaker

The line circuit breaker interrupts generator output if an overload or short circuit occurs. Use the line circuit breaker to manually disconnect the generator set from the load during generator set service. See Figure 7-13.

The circuit breaker must open all ungrounded connectors. Refer to Service Bulletin 611 for circuit breaker instantaneous overcurrent trip adjustment information.

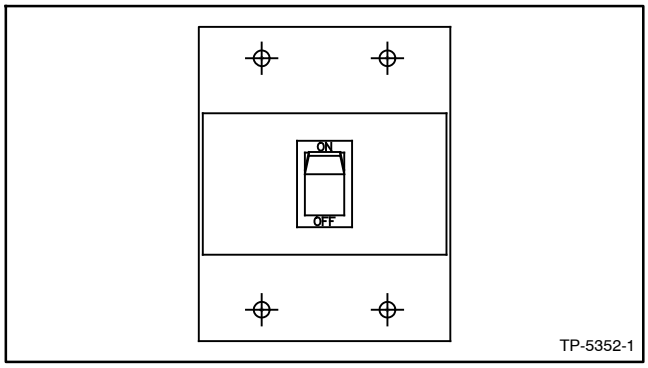

Figure 7-13 Line Circuit Breaker

7.9.4 Run Relay Kit

The run relay kit energizes only during generator set operation. The three sets of contacts typically control air intake and/or radiator louvers. However, alarms and other signaling devices can also connect to the contacts. See Figure 7-14.

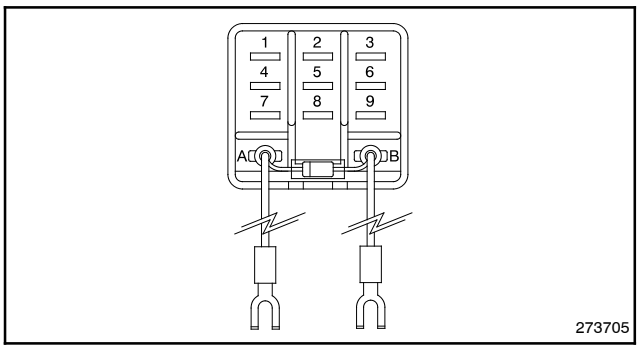

Figure 7-14 Run Relay Kit

7.9.5 Wireless Monitor

The wireless monitor system has two components: a wireless monitor unit and a website. The monitor unit transmits messages in response to signals received from the equipment controller and notifies designated recipients of selected operating conditions. The website monitors these messages.

There are three monitor models: GM23409-KP1 for use with hardwire inputs; GM23409-KP2 for use with a 550 controller using Modbus® communication; and GM23409-KP3 for use with a 550 controller using hardwire inputs that require a customer interface board.

Note: The 550 controller supports only one connection for Modbus® communication. If the controller's RS-485 connection is already used for Modbus® communication with other equipment, use wireless monitor model GM23409-KP1 or -KP3 with hardwire inputs through a customer connection board for monitoring.

Typical messages might include:

- Overcrank
- Low oil pressure
- Overspeed
- Common fault

At the website, the user configures which individuals will receive messages regarding selected operating conditions and the message delivery method. Delivery methods include pagers (alphanumeric, numeric), fax, XML, e-mail, PCS, or telephone (voice delivery). Each message sent will contain the condition that generated the transmission and also the make, model, and location of the equipment. Up to 40 messages each day can be delivered. Single or multiple messages can be sent to selected recipients via multiple delivery methods. More than one delivery method can be used for each recipient.

The wireless monitor is powered by the equipment power source or by the generator set and constantly monitors the inputs. When an input is triggered, the wireless monitor sends the condition over the North American AMPS (advanced mobile phone system). An operations center server receives the transmission and forwards the message to the selected recipients according to the configured delivery method.

Every 24 hours, the wireless monitor also sends information about itself and the system it is monitoring. This *heartbeat* transmission tells the Kohler center that the wireless monitor is properly functioning, powered, and able to generate messages. If a device fails to report a nightly heartbeat for more than a day, the system sends a *Unit Failed to Report Heartbeat* alarm message to the website.

Generator set run times and the number of cycles are reported. Models GM23409-KP1 and -KP3 accumulate run times over a 24-hour period and report the run times with the heartbeat message. Model GM23409-KP2 (for the 550 controller only) reports the total accumulated run time and the total number of starts. Run times for model GM23409-KP2 are also totaled using the Control Panel function and can be updated upon request.

Upon power loss, a rechargeable battery powers the wireless monitor. The monitor continues to transmit messages for 15 minutes, then transmits a loss of power signal and enters the *sleep* mode. The sleep mode can last up to 18 hours, until the battery completely discharges or power is restored. The wireless monitor continues to send scheduled heartbeat messages during the sleep mode until the battery discharges completely.

8.1 Accessories and Connections

Several accessories help finalize installation, add convenience to operation and service, and establish state and local code compliance.

Accessories vary with each generator set model and controller. Select factory-installed and/or shipped-loose accessories. See Figure 8-1 for a list of available kits. Obtain the most current accessory information from your local authorized service distributor/dealer.

This section illustrates several accessories available at print time of this publication. Accessory kits generally include installation instructions. See wiring diagrams manual for electrical connections not shown in this section. See the installation instructions and drawings supplied with kit for information on kit mounting location.

The instructions provided with the accessory kit supersede these instructions where there are differences. In general, run AC and DC wiring in separate conduit. Use shielded cable for all analog inputs. Observe all applicable national, state, and local electrical codes during accessory installation.

8.1.2 Common Failure Relay Kit

The common failure relay kit provides one set of contacts to trigger user-provided warning devices if a fault occurs. The common failure relay faults are user-defined. See the respective operation manual for status and faults available for this function.

Connect up to three common failure relay kits to the controller output. See Figure 8-4 and Figure 8-5. See Section 8.2, Accessory Connections, for terminal identification.

8.1.3 Controller (Customer) Connection Kit

The controller connection kit allows easy connection of controller accessories without accessing the controller terminal strip. The supplied wiring harness connects controller connector P23 and terminal strips TB1-3 and TB1-4 to the controller connection kit connector P25 and terminal strips TB6, TB7, TB8, and TB9. Connect all accessories (except the emergency stop kit) to the controller connection kit terminal strips. See Figure 8-6. See Section 8.2, Accessory Connections, for terminal identification.

8.1.4 Float/Equalize Battery Charger Kit with Alarm Option

The float/equalize battery charger with alarm option provides battery charging to the engine starting battery(ies) and connects to the controller for fault detection. Battery chargers for 12- or 24-volt models are available as a generator set accessory. See Figure 8-7. See Section 8.2, Accessory Connections, for terminal identification.

8.1.5 Ground Fault Annunciation

A relay contact for customer connection indicates a ground fault condition and is part of a ground fault alarm. See Figure 8-8 for electrical connections and the following procedure for controller setup. Use the instructions with the kit when provided to install and setup this accessory.

⚠ WARNING

Accidental starting.
Can cause severe injury or death.

Disconnect the battery cables before working on the generator set. Remove the negative (–) lead first when disconnecting the battery. Reconnect the negative (–) lead last when reconnecting the battery.

Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) Move the generator set master switch to the OFF position. (2) Disconnect the power to the battery charger. (3) Remove the battery cables, negative (–) lead first. Reconnect the negative (–) lead last when reconnecting the battery. Follow these precautions to prevent starting of the generator set by an automatic transfer switch, remote start/stop switch, or engine start command from a remote computer.

Ground Fault Controller Setup Procedure

1. Reconnect battery, if not already done.
2. Place the controller master switch to the AUTO position.
3. Press the Alarm Off key to silence the alarm horn, if necessary.
4. If the programming mode LED is not flashing, go to the step 5. If the programming mode LED is flashing, go to step 6.
5. Set Programming Mode to Local.
   a. Press keys RESET MENU, 1, 4, ENTER, MENU.
   b. Press key MENU until *Programming Mode–Local* is displayed.
   c. Press the YES key 7 YES, ENTER.
   d. When the *Enter Code* displays, press the factory default 0 LAMP TEST, ENTER or the user password keys and ENTER. The programming mode LED should be flashing.
6. Set digital input #6 to ground fault.
   a. Press RESET MENU, 9, ENTER. *Menu 9 Input Setup* should be displayed.
   b. Press MENU until *Digital Input 06 Warning* is displayed.
   c. Press MENU once to select this input.
   d. Press MENU until *Ground Fault* is displayed.
   e. Press 7 YES, ENTER to define Digital Input #06 as ground fault. *Entry Accepted* is displayed.
   f. Press MENU to display *Digital Input #06 Inhibit Time*.
   g. Press 0 LAMP TEST, ENTER to enter the inhibit time. *Entry Accepted* is displayed and the inhibit time *0:00* is now displayed.

h. Press MENU to display *Digital Input #06 Delay TIme*.

i. Press 5 ENTER to enter delay time. *Entry Accepted* is displayed. Default delay time is 5 sec.

j. Press RESET MENU.

7. Verify Programming.

   a. Move handle of ground fault circuit breaker at generator set to simulate a ground fault.

   b. Verify that display shows *D06 Ground Fault*. The System Warning LED should be illuminated and the alarm horn should sound. If these indicators are not present, recheck steps 6a. through 6j.

   c. Return handle of ground fault circuit breaker to the non-ground fault position. *D06 Ground Fault* display should now be cleared.

8. Set Programming Mode to Off.

   a. Press RESET MENU 1 4 ENTER.

   b. Press key MENU until *Programming Mode Off* is displayed.

   c. Press the YES key 7 YES ENTER.

   d. When the *Enter Code* displays, press the factory default 0 LAMP TEST ENTER or the user password keys and ENTER. The programming mode LED should now be off.

9. Place the controller master switch to the OFF/ RESET position.

10. Disconnect the battery negative (-) lead to power down the generator set.

11. After 2-3 minutes, reconnect the battery negative (-) lead.

12. Reset the controller clock. See Menu 6—Time and Date.

8.1.6 Idle (Speed) Mode Feature

The idle (speed) mode feature provides the ability to start and run the engine at idle (reduced) speed for a selectable time period (0–10 minutes) during warm-up. The controller will override the idle speed mode if the engine reaches the preprogrammed engine warmed-up temperature before the idle mode times out. See Figure 8-9 for user-supplied switch connection.

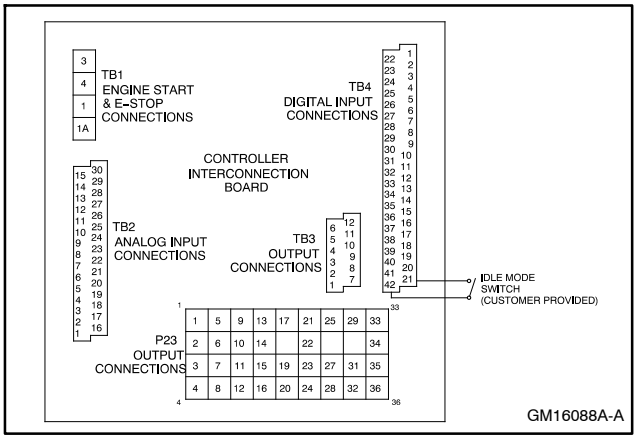

Figure 8-9 Idle (Speed) Mode Switch

8.1.7 Low Fuel (Level/Pressure) Switch

Some gaseous-fueled models offer a low fuel pressure switch. The low fuel pressure switch connects to the same terminal as the low fuel *level* switch on diesel- or gasoline-fueled models. See Figure 8-10 and Figure 8-11. See Section 8.2, Accessory Connections, for terminal identification.

Note: The main tank or the transfer/day tank includes the low fuel level switch. The fuel tank supplier typically provides the low fuel level switch.

8.1.8 Prime Power Switch Kit

The prime power switch kit prevents battery drain during generator set nonoperation periods and when the generator set battery cannot be maintained by an AC battery charger. See Figure 8-12 for an illustration of the kit and Figure 8-13 for the electrical connections.

1. Prime power decal (293668) 2. Toggle switch (354464)

Figure 8-12 Prime Power Switch Installation Location

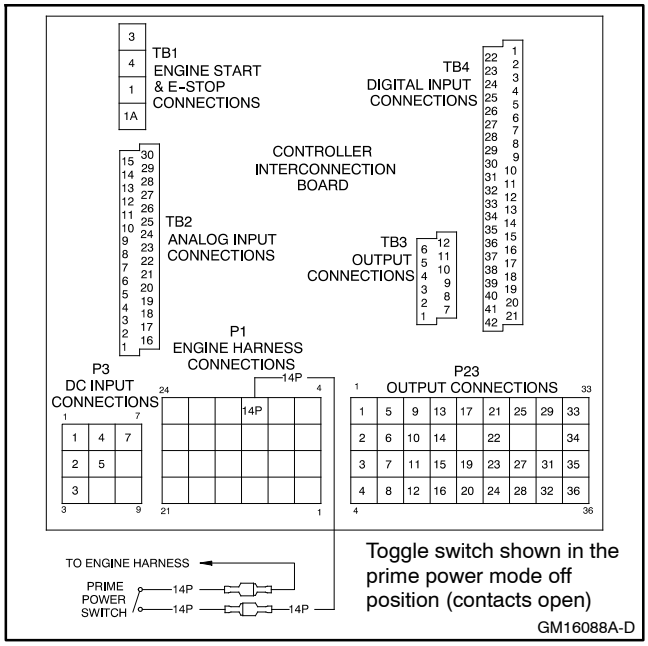

Figure 8-13 Prime Power Switch Connections

Stop the generator set using the stopping procedures in the respective operation manual before placing the generator set in the prime power mode. Move the prime power switch located on the back of the controller to the *DOWN* position. The controller including the digital display, LEDs, and alarm horn does not function when the generator set is in the prime power mode.

Move the prime power switch located on the back of the controller to the *UP* position and reset the controller time and date before attempting to start the generator set.

8.1.9 Remote Emergency Stop Kit

The emergency stop kit allows immediate shutdown of the generator set from a remote location. See Figure 8-14 and Figure 8-15. If the emergency stop switch activates, the EMERGENCY STOP lamp lights and the unit shuts down. Before attempting to restart the generator set, reset the emergency stop switch (by replacing the glass piece) and reset the generator set by placing the master switch in the OFF/RESET position.

Use the single glass piece located inside the switch for replacement and order additional glass pieces as service parts. See the respective operation manual for the Emergency Stop Switch Reset Procedure. See Section 8.2, Accessory Connections, for terminal identifications.

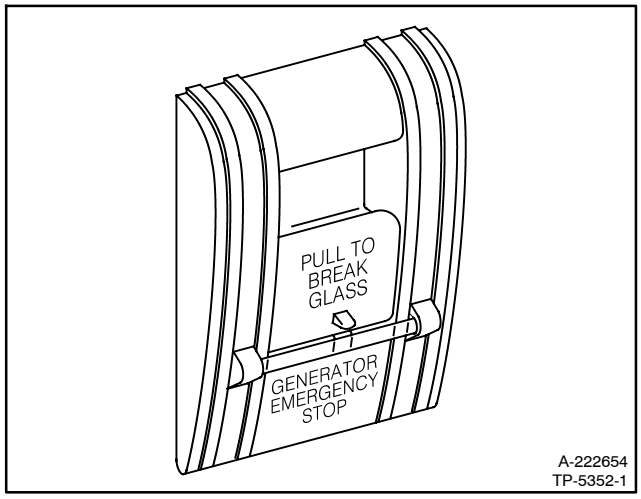

Figure 8-14 Emergency Stop Kit

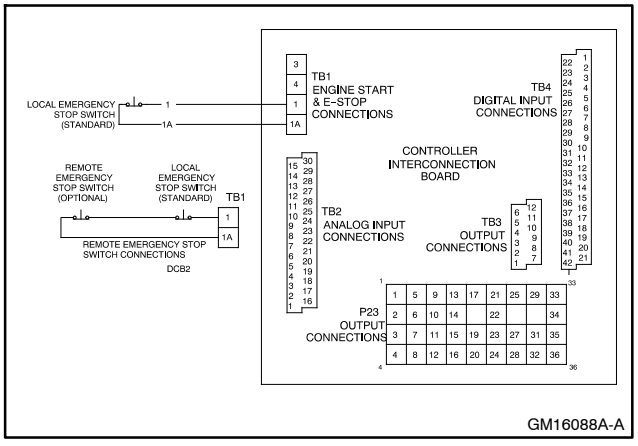

Figure 8-15 Remote Emergency Stop Kit Connections

8.1.10 Remote Reset Feature

The remote reset switch provides generator set resetting after a fault shutdown at a remote location. See Figure 8-16 and Figure 8-17 for user-supplied switch connection.

Press and hold the switch for 2–3 seconds and release to reset the generator set controller.

8.1.11 Remote Serial Annunciator (RSA III)

Adapted from Instruction TT-1625 9/14b.

The following information summarizes the setup items when installing the remote serial annunciator. Refer to the RSA installation instructions TT-1625 for operation and function.

RSA III Features and Connections

RSA III is an annunciator panel offered in several kit configurations to support Kohler power equipment. The RSA III is a remote serial annunciator that monitors the condition of the generator set and/or ATS from a remote location. The RSA III alerts the operator through visual and audible signals using LED indication and a horn. An alarm silence and lamp test switch are included.

An RSA III annunciator can be used for a single generator set (Figure 8-18) or with a combination of a generator set and automatic transfer switch(es) (Figure 8-19 or Figure 8-20). In systems using more than a single RSA III, one must be designated as the master device to broadcast to additional RSA III annunciators, designated as slave devices. Up to five RSA III slave devices can be used with an RSA III master device. All RSA III annunciators are factory set as the master device, but can be changed to a slave device using a PC and SiteTech™ software that connects to the RSA III front panel via a universal serial bus (USB) connection.

The RSA II can be connected with the RSA III provided that the master remote annunciator is an RSA III.

The RSA III meets NFPA 110, Level 1 (2005) applications that require remote controls and alarms be powered by a storage battery such as the engine starting battery. AC adaptor kit GM62466-KP1 is available when NFPA is not required.

See Section 8.2, Accessory Connections, for terminal identifications.

A PC with SiteTech™ software is required to make the RSA III functional. Use your SecurID to access KOHLERnet, click on the TechTools button, and follow the instructions to download the files. See SiteTech™ Software Settings and refer to TP-6701 SiteTech™ Software Operation Manual for more information.

If a fault occurs, the RSA III horn activates and the corresponding LED illuminates. The following paragraphs describe specific features of the RSA III.

If the RSA III is used with an Ethernet communication network, order Modbus® Ethernet converter GM41143-KP2 and refer to TT-1405 Converters, Connections, and Controller Setup for Network Communication for system installation.

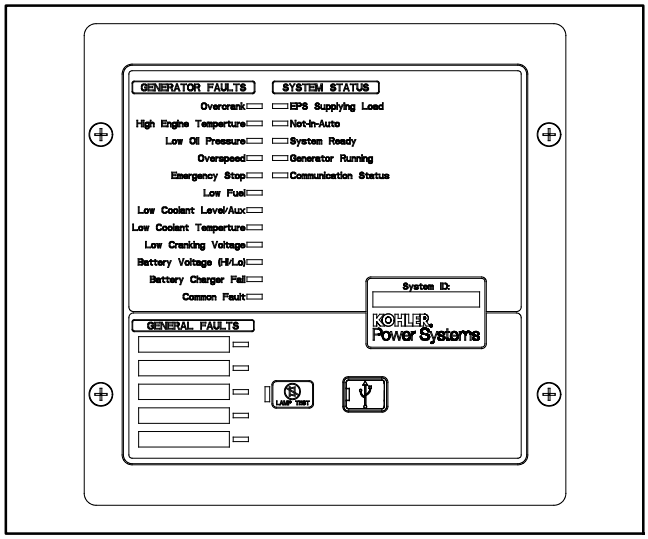

Figure 8-18 Remote Serial Annunciator (RSA III)

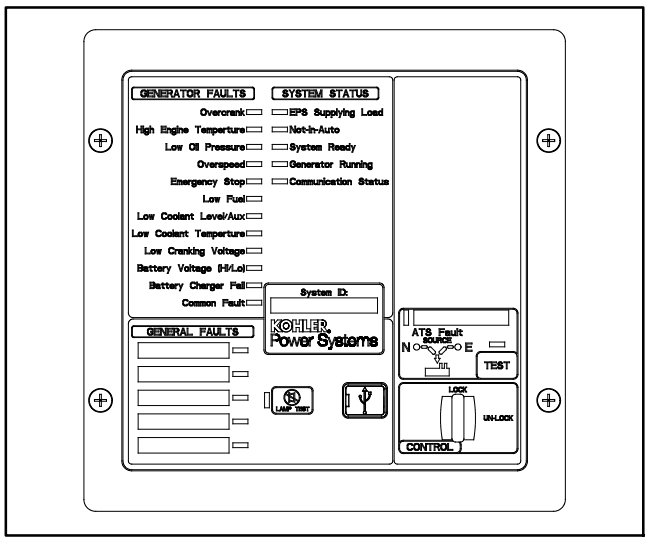

Figure 8-19 RSA III with Single ATS Control

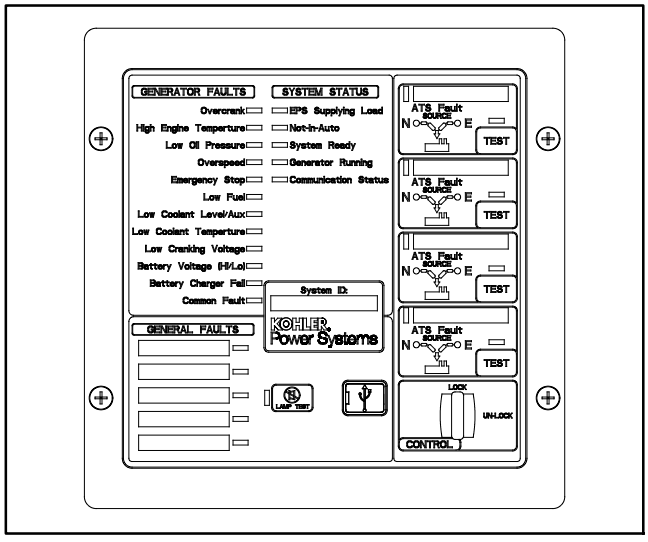

Figure 8-20 RSA III with Four ATS Controls

Modbus® is a registered trademark of Schneider Electric.

If there is only one RSA III, it is the master. If several RSA III are installed, choose either the RSA III closest to the generator set or determine which RSA III is more practical for use as a master and use a daisy chain wiring configuration for the remaining RSAs. The RSA III connected to the controller MUST be assigned as the RSA III master.

Note: When an RSA III is installed into a system with existing older RSAs, the RSA III must be configured as the master.

Note: Should any communication issues occur when adding RSA III slaves and/or transfer switches to the system, be sure to power down the RSA III master and then power up the RSA III master so that the RSA III master can recognize the changes.

Use the SiteTech™ software to select either that the generator set controller activates EPS Supplying Load LED or the transfer switch activates LED or local EPS supplying load.

Use the SiteTech™ software to select the high speed mode for direct connection to the DEC 550 controller. Select lower speed for network connection with the Modbus®/ Ethernet converter. The lower speed allows network functionality reducing loss of communication faults.

Terminating Resistor and Wiring

For communication between the controller and RSA III master, see Figure 8-21. For communication between RSA III Master and RSA III Slave, see Figure 8-22. Place the terminating resistor on the last RSA III slave in the daisy chain connection.

Note: When using RS-485 communication cable, connect the “shield” wire at either end but not at both ends.

8.1.12 Shunt-Trip Line Circuit Breaker

A shunt-trip line circuit breaker provides a 12- or 24-DC volt solenoid within the line circuit breaker case that can energize the trip mechanism. This feature allows the circuit breaker to be tripped by a customer-selected fault such as alternator overload, overspeed, overvoltage, or defined common fault. Connection requires a shunt-trip wiring kit and a dry contact kit. See Figure 8-24.

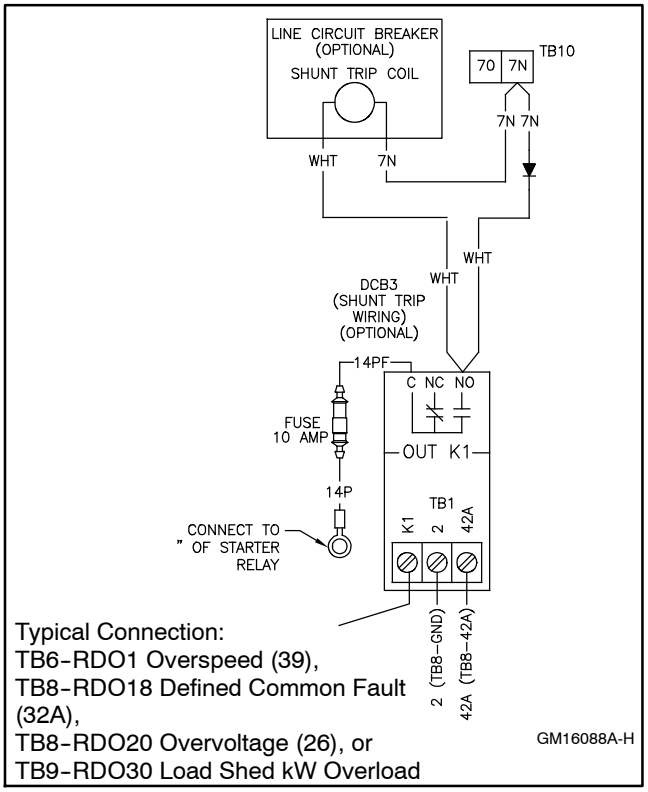

Figure 8-24 Shunt-Trip Line Circuit Breaker and Shunt-Trip Wiring Kit Connections

8.1.13 Single-Relay Dry Contact Kit

The single-relay dry contact kit provides normally open and normally closed contacts in a form C configuration to activate warning devices and other user- provided accessories allowing remote monitoring of the generator set. Typically, lamps, audible alarms, or other devices signal faults or status conditions. Connect any controller fault output to the single-relay dry contact kit.

A total of three dry contact kits may connect to a single controller output. See Figure 8-25 and Figure 8-26. See Section 8.2, Accessory Connections, for terminal identifications.

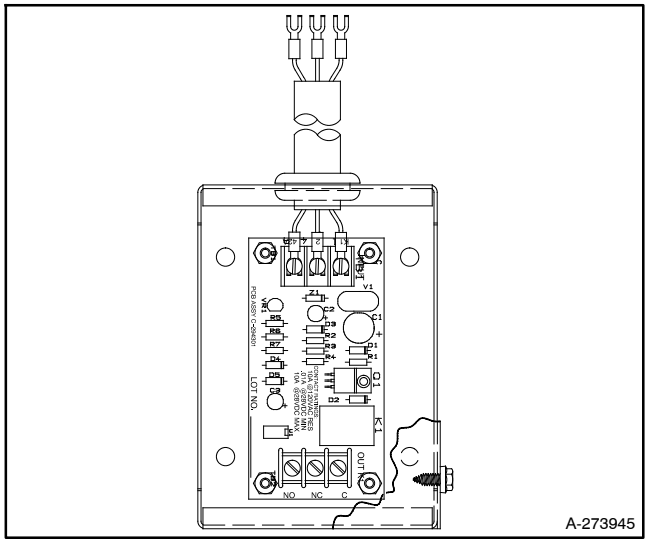

Figure 8-25 Single-Relay Dry Contact Kit, Typical

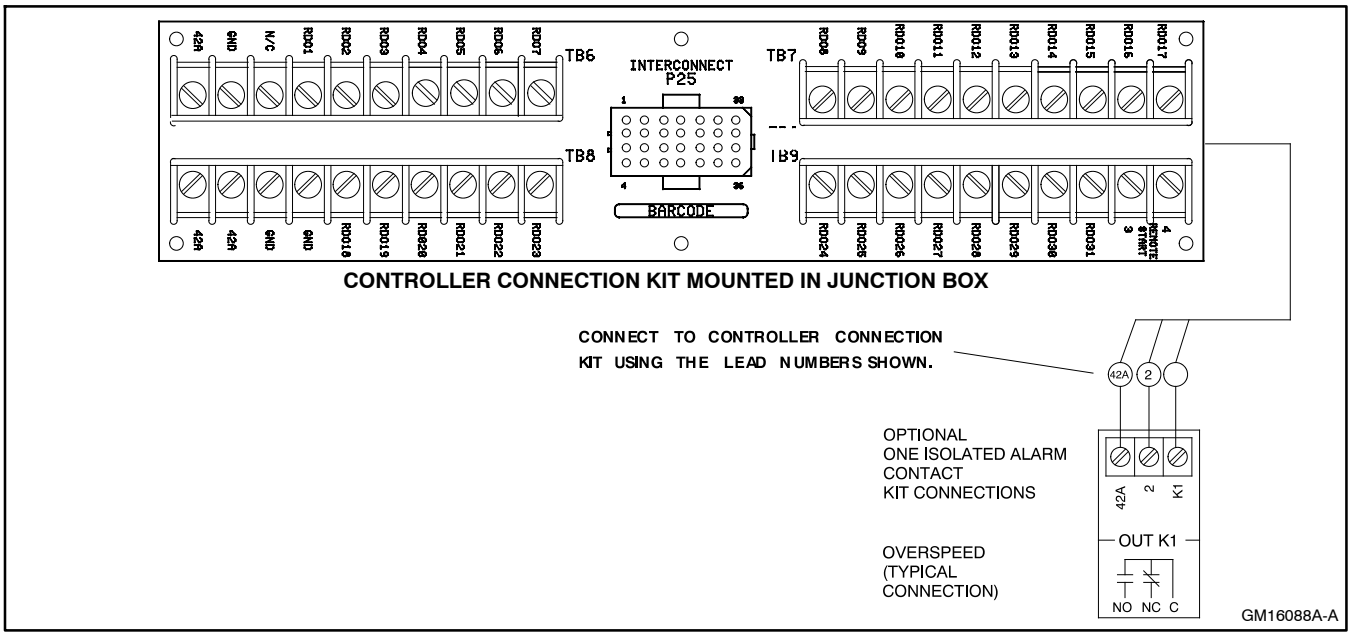

Figure 8-26 Single-Relay Dry Contact Kit Connections

8.1.14 Ten-Relay Dry Contact Kit

The ten-relay dry contact kit provides normally open and normally closed contacts in a form C configuration to activate warning devices and other user-provided accessories allowing remote monitoring of the generator set. Connect any controller fault output to the ten-relay dry contact kit. Typically, lamps, audible alarms, or other devices signal the fault conditions.

Refer to Figure 8-27 for an internal view of the contact kit. See Figure 8-28 for electrical connections. See Section 8.2, Accessory Connections, for terminal identifications.

8.1.15 Twenty-Relay Dry Contact Kit

The twenty-relay dry contact kit provides normally open and normally closed contacts in a form C configuration to activate warning devices and other user-provided accessories allowing remote monitoring of the generator set. Typically, lamps, audible alarms, or other devices signal faults or status conditions. Connect any generator set fault output to the dry contact kit.

Refer to Figure 8-29 for an internal view of the contact kit. See Figure 8-30 for electrical connections. See Section 8.2, Accessory Connections, for terminal identifications.

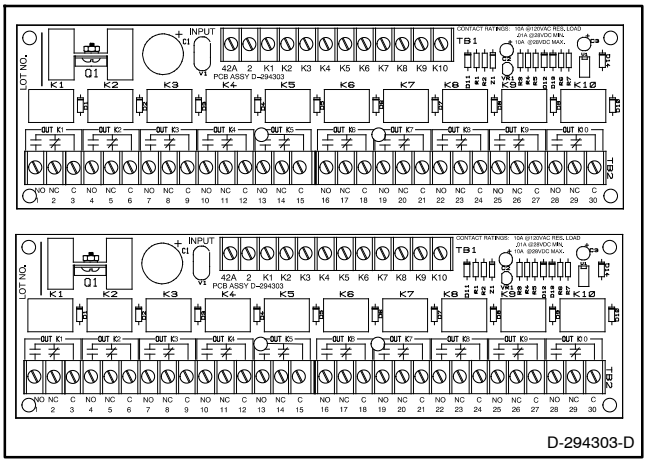

Figure 8-29 Twenty-Relay Dry Contact Kits

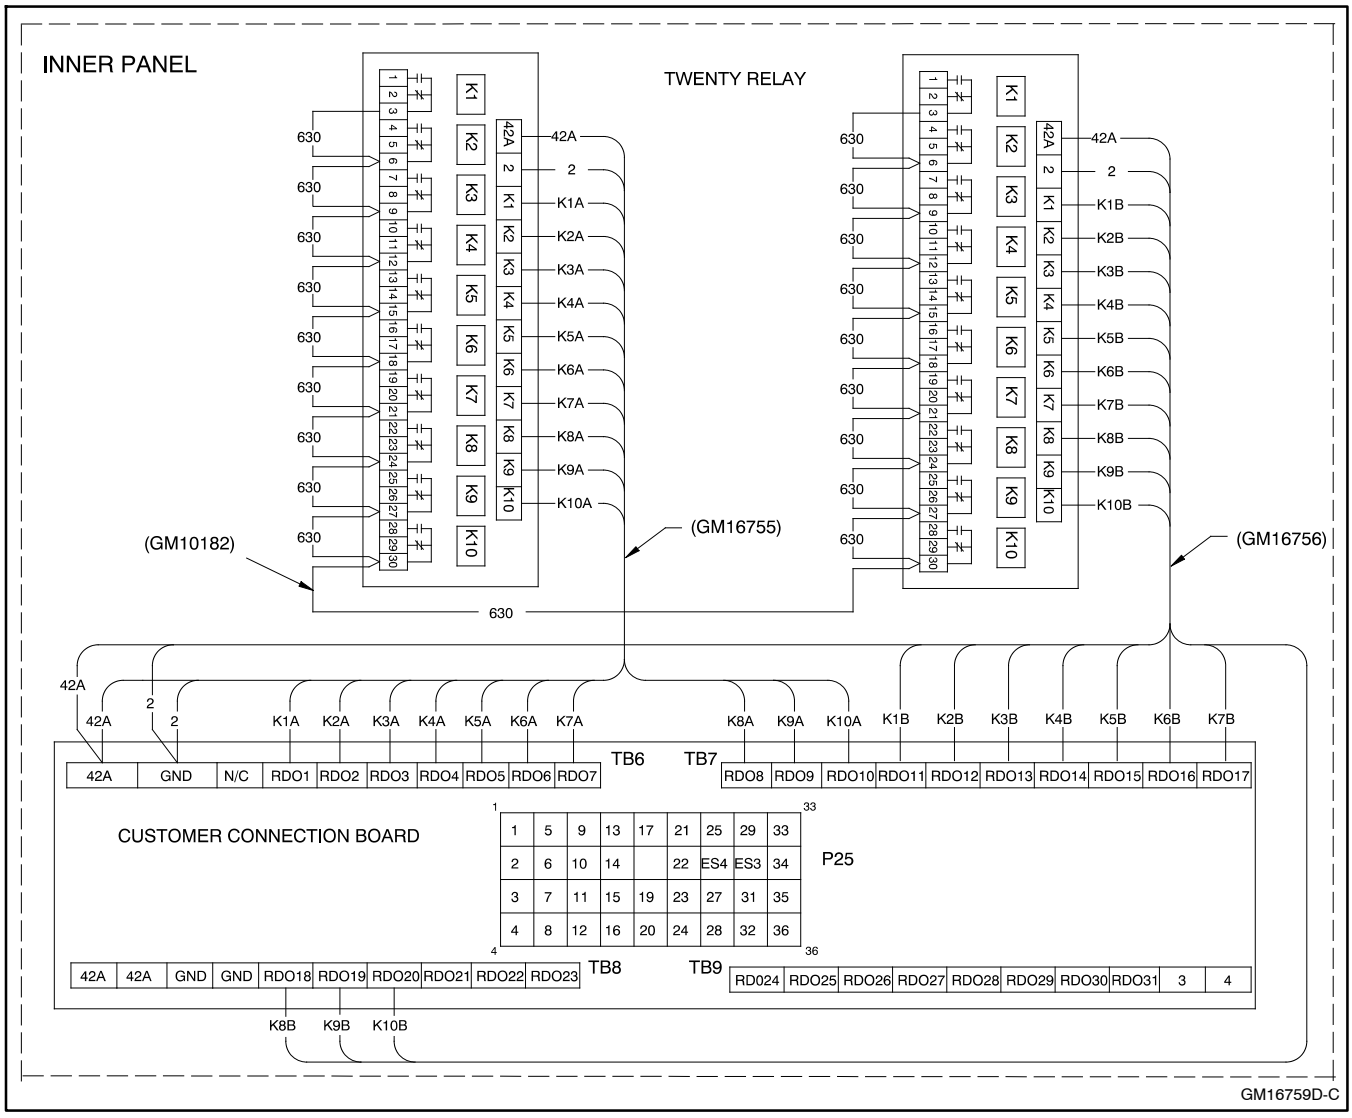

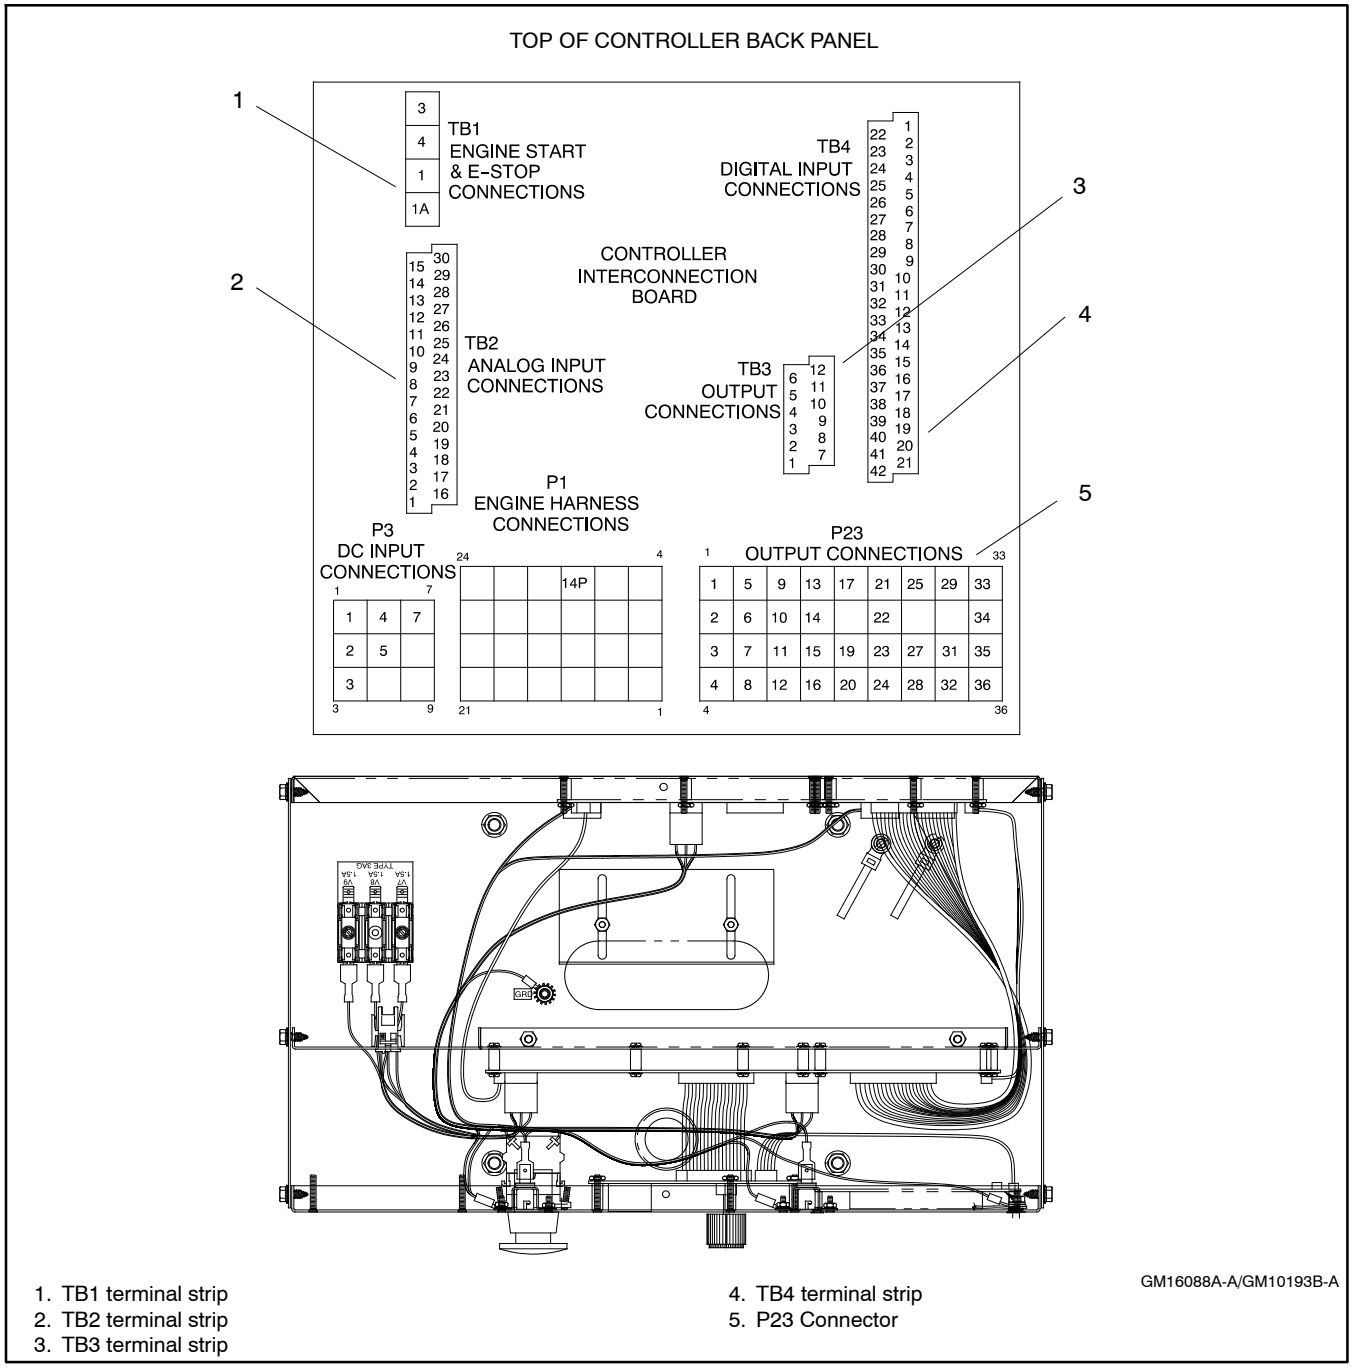

Figure 8-30 Twenty-Relay Dry Contact Relay Kit Connections

8.2 Accessory Connections

The 550 controller contains circuit boards equipped with terminal strip(s) for use in connecting a controller connection kit. Do not connect accessories directly to the controller terminal strip(s). Connect accessories to either a controller connection kit or a dry contact kit. Connect the dry contact kit(s) to the controller connection kit. Connect alarms, battery chargers, remote switches, and other accessories to the dry contact kit relay(s).

For specific information on accessory connections, refer to the accessory wiring diagrams in the wiring diagram manual and the instruction sheet accompanying the kit. See Figure 8-31 and Figure 8-32 for controller interconnection circuit board connections. See Figure 8-33 and Figure 8-34 for controller (customer) connection kit connections. See NO TAG, NO TAG, and Appendix G Wiring Diagrams for accessory connection wiring diagrams.

9.1 Accessories and Connections

Several accessories help finalize installation, add convenience to operation and service, and establish state and local code compliance.

Accessories vary with each generator set model and controller. Select factory-installed and/or shipped-loose accessories. See Figure 9-1 for a list of available kits. Obtain the most current accessory information from your local authorized service distributor/dealer.

This section illustrates several accessories available at print time of this publication. Accessory kits generally include installation instructions. See wiring diagrams manual for electrical connections not shown in this section. See the installation instructions and drawings supplied with kit for information on kit mounting location.

The instructions provided with the accessory kit supersede these instructions where there are differences. In general, run AC and DC wiring in separate conduit. Use shielded cable for all analog inputs. Observe all applicable national, state, and local electrical codes during accessory installation.

See Section 9.2, Accessory Connections, for terminal identification.

9.1.1 Common Fault/Failure (32A) Relay

The common fault relay is standard on the controller circuit board and located at the TB2 terminal strip connections. Contacts are rated at 2 amps at 32 VDC or 0.5 amps at 120 VAC max. See Figure 9-2 and Figure 9-3.

The optional common fault relay shown in Figure 9-3 as DCB2 has contacts rated at 10 amps at 28 VDC or 120 VAC and can be connected to user-supplied accessories.

The optional common fault relay shown in Figure 9-3 as DCB1 has contacts rated at 10 amps at 28 VDC or 120 VAC and is used to trigger the shunt-trip line circuit breaker kit (mentioned later in this section).

9.1.2 Float/Equalize Battery Charger Kit with Alarm Option

The float/equalize battery charger with alarm option provides battery charging to the engine starting battery(ies) and connects to the controller for fault detection. Battery chargers for 12- or 24-volt models are available as a generator set accessory. See Figure 9-4 and Figure 9-5 for battery connections.

9.1.3 Input/Output (I/O) Module Board

The I/O module board provides a generator set mounted panel with two analog or digital inputs and five digital outputs. See Figure 9-6 for circuit board components and electrical connections to the controller. See Figure 9-7 for connections of analog inputs. Refer to Figure 9-27 for accessory connections.

9.1.4 Low Fuel (Level/Pressure) Switch

Some gas-fueled models offer a low fuel pressure switch. The low fuel pressure switch connects to the same controller terminal as the low fuel *level* switch on diesel-fueled models. See Figure 9-8, Figure 9-9, and Figure 9-10.

Note: The main tank or the transfer/day tank includes the low fuel level switch. The fuel tank supplier typically provides the low fuel level switch.

9.1.5 Prime Power Switch Kit

The prime power switch kit prevents battery drain during generator set non–operation periods and when the generator set battery cannot be maintained by an AC battery charger. See Figure 9-11 for an illustration of the kit and Figure 9-12 for the electrical connections.

Stop the generator set using the stopping procedures in respective operation manual before placing the generator set in the prime power mode. Move the prime power switch located on the junction box to the *DOWN* position. The controller including the digital display, LEDs, and alarm horn does not function when the generator set is in the prime power mode.

Move the prime power switch located on the junction box to the *UP* position. The generator set is now ready for starting.

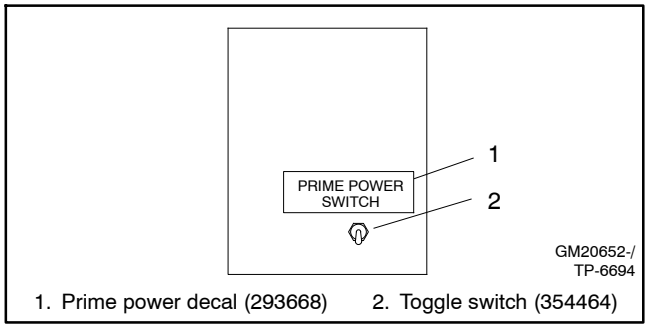

Figure 9-11 Prime Power Switch

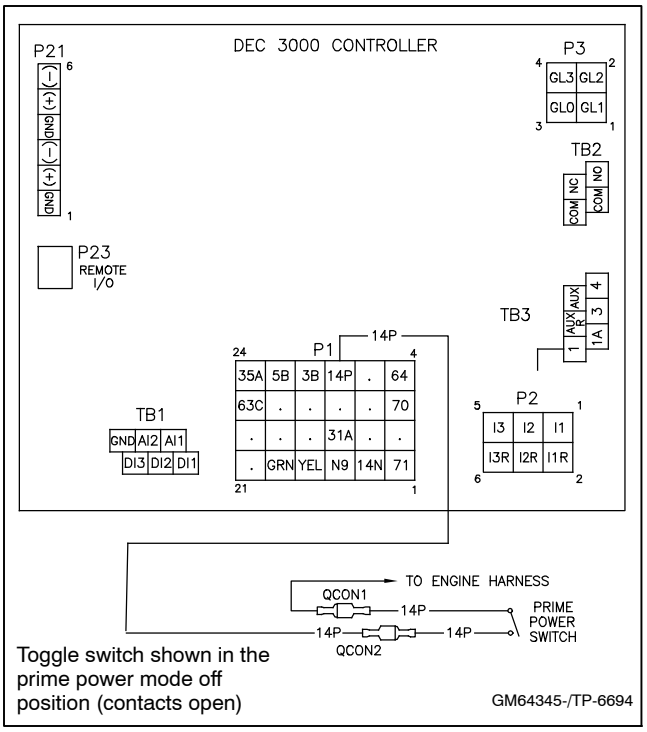

Figure 9-12 Prime Power Switch Connections

9.1.6 Remote Emergency Stop Kit

The emergency stop kit allows immediate shutdown of the generator set from a remote location. See Figure 9-13 and Figure 9-14. If the emergency stop switch activates, the EMERGENCY STOP lamp lights and the unit shuts down. Before attempting to restart the generator set, reset the emergency stop switch (by replacing the glass piece) and reset the generator set by pressing the master control switch OFF/RESET button.

Use the single glass piece located inside the switch for replacement and order additional glass pieces as service parts. See the respective operation manual for Emergency Stop Switch Resetting.

See Section 9.2, Accessory Connections, for terminal identifications.

9.1.8 Remote Serial Annunciator (RSA III)

Adapted from Instruction TT-1625 9/14.

The following information summarizes the setup items when installing the remote serial annunciator. Refer to the RSA installation instructions TT-1625 for operation and function.

RSA III Features and Connections

RSA III is an annunciator panel offered in several kit configurations to support Kohler power equipment. The RSA III is a remote serial annunciator that monitors the condition of the generator set and/or ATS from a remote location. The RSA III alerts the operator through visual and audible signals using LED indication and a horn. An alarm silence and lamp test switch are included.

An RSA III annunciator can be used for a single generator set (Figure 9-17) or with a combination of a generator set and automatic transfer switch(es) (Figure 9-18 or Figure 9-19). In systems using more than a single RSA III, one must be designated as the master device to broadcast to additional RSA III annunciators, designated as slave devices. Up to five RSA III slave devices can be used with an RSA III master device. All RSA III annunciators are factory set as the master device, but can be changed to a slave device using a PC and SiteTech™ software that connects to the RSA III front panel via a universal serial bus (USB) connection.

The RSA II can be connected with the RSA III provided that the master remote annunciator is an RSA III.

The RSA III meets NFPA 110, Level 1 (2005) applications that require remote controls and alarms be powered by a storage battery such as the engine starting battery. AC adaptor kit GM62466-KP1 is available when NFPA is not required.

See Section 9.2, Accessory Connections, for terminal identifications.

A PC with SiteTech™ software is required to make the RSA III functional. Use your SecurID to access KOHLERnet, click on the TechTools button, and follow the instructions to download the files. See SiteTech™ Software Settings and refer to TP-6701 SiteTech™ Software Operation Manual for more information.

If a fault occurs, the RSA III horn activates and the corresponding LED illuminates. The following paragraphs describe specific features of the RSA III.

If the RSA III is used with an Ethernet communication network, order Modbus® Ethernet converter GM41143-KP2 and refer to TT-1405 Converters, Connections, and Controller Setup for Network Communication for system installation.

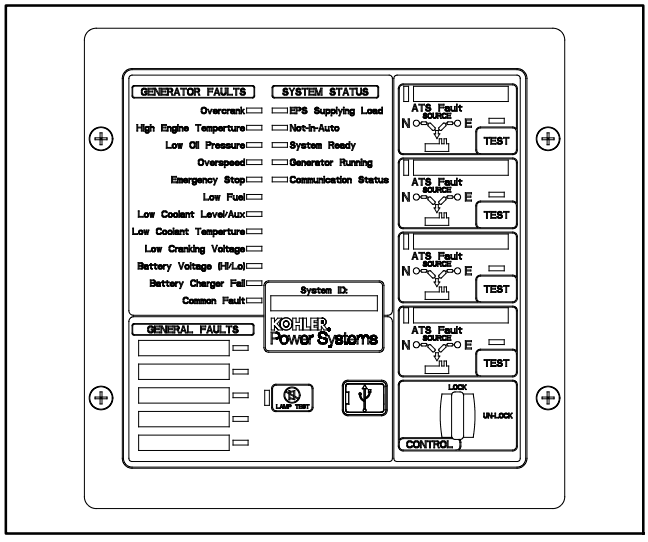

Figure 9-19 RSA III with Four ATS Controls

Modbus® is a registered trademark of Schneider Electric.

If there is only one RSA III, it is the master. If several RSA III are installed, choose either the RSA III closest to the generator set or determine which RSA III is more practical for use as a master and use a daisy chain wiring configuration for the remaining RSAs. The RSA III connected to the controller MUST be assigned as the RSA III master.

Note: When an RSA III is installed into a system with existing older RSAs, the RSA III must be configured as the master.

Note: Should any communication issues occur when adding RSA III slaves and/or transfer switches to the system, be sure to power down the RSA III master and then power up the RSA III master so that the RSA III master can recognize the changes.

Use the SiteTech™ software to select either that the generator set controller activates EPS Supplying Load LED or the transfer switch activates LED or local EPS supplying load.

Use the SiteTech™ software to select the high speed mode for direct connection to the DEC 3000 controller. Select lower speed for network connection with the Modbus®/Ethernet converter. The lower speed allows network functionality reducing loss of communication faults.

Terminating Resistor and Wiring

For communication between the controller and RSA III master, see Figure 9-20. For communication between RSA III Master and RSA III Slave, see Figure 9-21. Place the terminating resistor on the last RSA III slave in the daisy chain connection.

Note: When using RS-485 communication cable, connect the “shield” wire at either end but not at both ends.

9.1.9 Shunt-Trip Line Circuit Breaker

A shunt-trip line circuit breaker provides a 12- or 24-DC volt solenoid within the line circuit breaker case that can energize the trip mechanism. This feature allows the circuit breaker to be tripped by the common fault (32A). Connection requires a shunt-trip wiring kit and a dry contact kit. See Figure 9-23 and Figure 9-24.

The optional common fault relay shown in Figure 9-24 as DCB1 has contacts rated at 10 amps at 28 VDC or 120 VAC and is used to trigger the shunt-trip line circuit breaker kit.

9.2 Accessory Connections

The controller contains a circuit board equipped with terminal strip(s) for use in connecting external optional accessories including alarms, battery chargers, and remote switches. The optional I/O board provides an additional two analog or digital inputs and five digital outputs.

For specific information on accessory connections, refer to the accessory wiring diagrams in the wiring diagram manual and the instruction sheet accompanying the kit. See Figure 9-25, Figure 9-26, and NO TAG for controller circuit board connections.

10.1 Accessories and Connections

Several accessories help finalize installation, add convenience to operation and service, and establish state and local code compliance.

Accessories vary with each generator set model and controller. Select factory-installed and/or shipped-loose accessories. See Figure 7-8 for a list of available kits. Obtain the most current accessory information from your local authorized service distributor/dealer.

This section illustrates several accessories available at print time of this publication. Accessory kits generally include installation instructions. See wiring diagrams manual for electrical connections not shown in this section. See the installation instructions and drawings supplied with kit for information on kit mounting location.

The instructions provided with the accessory kit supersede these instructions where there are differences. In general, run AC and DC wiring in separate conduit. Use shielded cable for all analog inputs. Observe all applicable national, state, and local electrical codes during accessory installation.

See Section 8.2, Accessory Connections, for terminal identification.

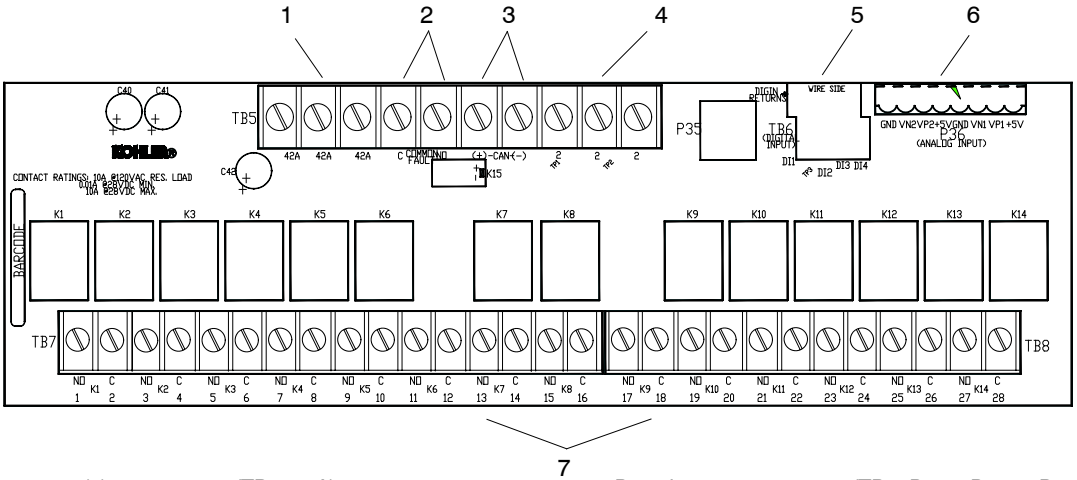
10.1.1 Fifteen-Relay Dry Contact



The 15-relay dry contact board has four digital inputs and two analog inputs. There are 14 individual relay driver outputs (RDOs) with one common fault RDO.

See Figure 9-6 for circuit board components and electrical connections to the controller. See Figure 9-7 for connections of analog inputs.

See Section 8.2, Accessory Connections, for terminal identification.

10.1.2 Remote Emergency Stop Kit

The emergency stop (E-stop) kit allows immediate shutdown of the generator set from a remote location. See Figure 8-15. If the emergency stop switch activates, the EMERGENCY STOP lamp lights and the unit shuts down. Before attempting to restart the generator set, reset the emergency stop switch (by replacing the glass piece) and reset the generator set by pressing the master control switch OFF/RESET button.

Use the single glass piece located inside the switch for replacement and order additional glass pieces as service parts. See the respective operation manual for the Emergency Stop Switch Reset Procedure.

See Section 10.2, Accessory Connections, for terminal identifications.

11.1 Accessories and Connections

Several accessories help finalize installation, add convenience to operation and service, and establish state and local code compliance.

Accessories vary with each generator set model and controller. Select factory-installed and/or shipped-loose accessories. See Figure 11-1 for a list of available kits. Obtain the most current accessory information from your local authorized service distributor/dealer.

This section illustrates several accessories available at print time of this publication. Accessory kits generally include installation instructions. See wiring diagrams manual for electrical connections not shown in this section. See the installation instructions and drawings supplied with kit for information on kit mounting location.

The instructions provided with the accessory kit supersede these instructions where there are differences. In general, run AC and DC wiring in separate conduit. Use shielded cable for all analog inputs. Observe all applicable national, state, and local electrical codes during accessory installation.

11.1.1 Audiovisual Alarm Kit

An audiovisual alarm warns the operator at a remote location of fault shutdowns and prealarm conditions. Audiovisual alarms include an alarm horn, an alarm silence switch, and common fault lamp. See Figure 11-2 and Figure 11-3. See Section 11.2, Accessory Connections, for terminal identification.

Note: Use the audiovisual alarm with a dry contact kit.

11.1.2 Common Failure Relay Kit

The common failure relay kit provides one set of contacts to trigger user-provided warning devices if a fault occurs. The common failure relay faults are user-defined. See Section 2, Operation, Menu 10—Output Setup, for status and faults available for this function.

Connect up to three common failure relay kits to the controller output. See Figure 11-4 and Figure 11-5. See Section 11.2, Accessory Connections, for terminal identification.

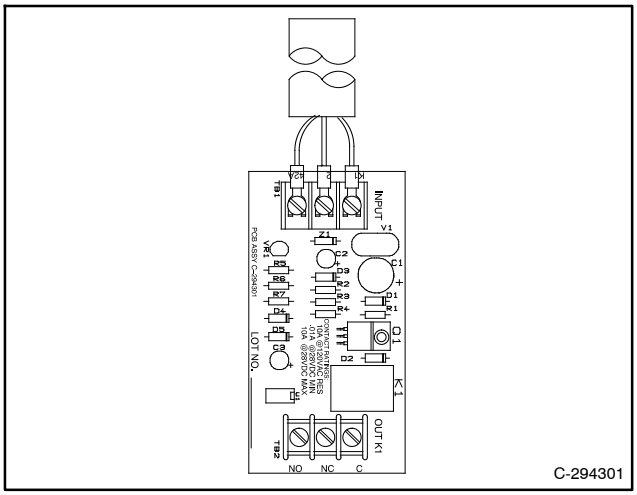

Figure 11-4 Common Failure Relay Kit

11.1.3 Float/Equalize Battery Charger Kit with Alarm Option

The float/equalize battery charger with alarm option provides battery charging to the engine starting battery(ies) and connects to the controller for fault detection. Battery chargers for 12- or 24-volt models are available as a generator set accessory. See Figure 11-6. See Section 11.2, Accessory Connections, for terminal identification.

11.1.4 Ground Fault Annunciation

A relay contact for customer connection indicates a ground fault condition and is part of a ground fault alarm. See Figure 11-7 for electrical connections and the following procedure for controller setup. Use the instructions with the kit when provided to install and setup this accessory.

⚠ WARNING

Accidental starting.
Can cause severe injury or death.

Disconnect the battery cables before working on the generator set. Remove the negative (-) lead first when disconnecting the battery. Reconnect the negative (-) lead last when reconnecting the battery.

Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) Press the generator set off/reset button to shut down the generator set. (2) Disconnect the power to the battery charger, if equipped. (3) Remove the battery cables, negative (-) lead first. Reconnect the negative (-) lead last when reconnecting the battery. Follow these precautions to prevent the starting of the generator set by the remote start/stop switch.

Ground Fault Controller Setup Procedure

1. Reconnect battery, if not already done.
2. Press the controller master switch AUTO button.
3. Press the Alarm Off key to silence the alarm horn, if necessary.
4. If the programming mode LED is not flashing, go to the step 5. If the programming mode LED is flashing, go to step 6.
5. Set Programming Mode to Local.
   a. Press keys RESET MENU, 1, 4, ENTER, MENU.
   b. Press key MENU until *Programming Mode-Local* is displayed.
   c. Press the YES key 7 YES, ENTER.
   d. When the *Enter Code* displays, press the factory default 0 LAMP TEST, ENTER or the user password keys and ENTER. The programming mode LED should be flashing.
6. Set digital input #6 to ground fault.
   a. Press RESET MENU, 9, ENTER. *Menu 9 Input Setup* should be displayed.
   b. Press MENU until *Digital Input 06 Warning* is displayed.
   c. Press MENU once to select this input.
   d. Press MENU until *Ground Fault* is displayed.
   e. Press 7 YES, ENTER to define Digital Input #06 as ground fault. *Entry Accepted* is displayed.
   f. Press MENU to display *Digital Input #06 Inhibit Time*.
   g. Press 0 LAMP TEST, ENTER to enter the inhibit time. *Entry Accepted* is displayed and the inhibit time *0:00* is now displayed.

h. Press MENU to display *Digital Input #06 Delay TIme*.

i. Press 5 ENTER to enter delay time. *Entry Accepted* is displayed. Default delay time is 5 sec.

j. Press RESET MENU.

7. Verify Programming.

   a. Move handle of ground fault circuit breaker at generator set to simulate a ground fault.

   b. Verify that display shows *D06 Ground Fault*. The System Warning LED should be illuminated and the alarm horn should sound. If these indicators are not present, recheck steps 6a. through 6j.

   c. Return handle of ground fault circuit breaker to the non-ground fault position. *D06 Ground Fault* display should now be cleared.

8. Set Programming Mode to Off.

   a. Press RESET MENU 1 4 ENTER.

   b. Press key MENU until *Programming Mode Off* is displayed.

   c. Press the YES key 7 YES ENTER.

   d. When the *Enter Code* displays, press the factory default 0 LAMP TEST ENTER or the user password keys and ENTER. The programming mode LED should now be off.

9. Press the controller master switch OFF button.

10. Disconnect the battery negative (–) lead to power down the generator set.

11. After 2-3 minutes, reconnect the battery negative (–) lead.

12. Reset the controller clock. See Menu 6—Time and Date.

11.1.5 Idle (Speed) Mode Feature

The idle (speed) mode feature provides the ability to start and run the engine at idle (reduced) speed for a selectable time period (0–10 minutes) during warm-up. The controller will override the idle speed mode if the engine reaches the preprogrammed engine warmed-up temperature before the idle mode times out. See Figure 11-8 for user-supplied switch connection.

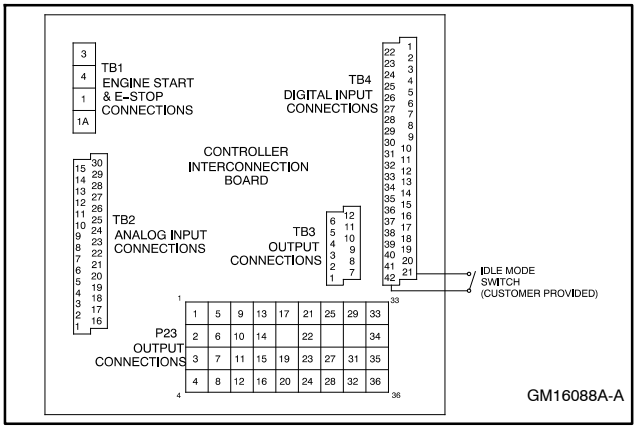

Figure 11-8 Idle (Speed) Mode Switch

11.1.6 Low Fuel (Level/Pressure) Switch

Some gaseous-fueled models offer a low fuel pressure switch. The low fuel pressure switch connects to the same terminal as the low fuel *level* switch on diesel- or gasoline-fueled models. See Figure 11-9 and Figure 11-10. See Section 11.2, Accessory Connections, for terminal identification.

Note: The main tank or the transfer/day tank includes the low fuel level switch. The fuel tank supplier typically provides the low fuel level switch.

11.1.7 Prime Power Switch Kit

The prime power switch kit prevents battery drain during generator set nonoperation periods and when the generator set battery cannot be maintained by an AC battery charger. See Figure 11-11 for an illustration of the kit and Figure 11-12 for the electrical connections.

1. Prime power decal (293668) 2. Toggle switch (354464)

Stop the generator set using the stopping procedures in the respective operation manual before placing the generator set in the prime power mode. Move the prime power switch located on the back of the controller to the *DOWN* position. The controller including the digital display, LEDs, and alarm horn does not function when the generator set is in the prime power mode.

Move the prime power switch located on the back of the controller to the *UP* position and reset the controller time and date before attempting to start the generator set.

11.1.8 Remote Emergency Stop Kit

The emergency stop kit allows immediate shutdown of the generator set from a remote location. See Figure 11-13 and Figure 11-14. If the emergency stop switch activates, the EMERGENCY STOP lamp lights and the unit shuts down. Before attempting to restart the generator set, reset the emergency stop switch (by replacing the glass piece) and reset the generator set by placing the master switch in the OFF/RESET position.

Use the single glass piece located inside the switch for replacement and order additional glass pieces as service parts. See the respective operation manual for the Emergency Stop Switch Reset Procedure. See Section 11.2, Accessory Connections, for terminal identifications.

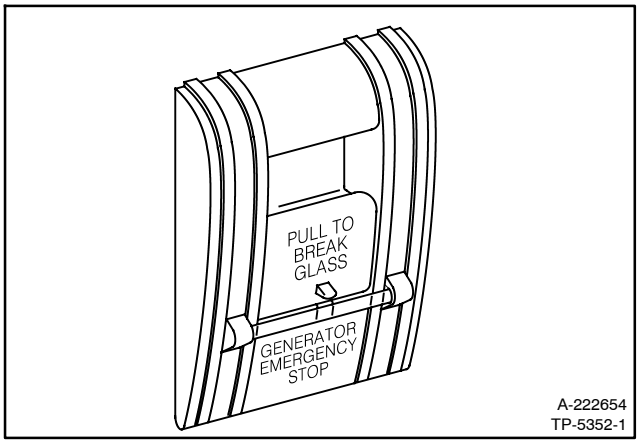

Figure 11-13 Emergency Stop Kit

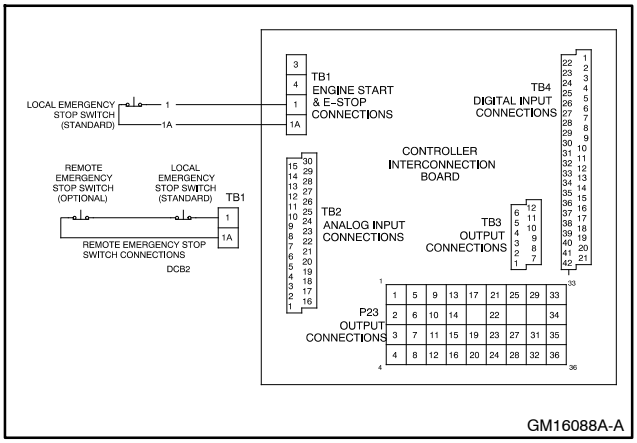

Figure 11-14 Remote Emergency Stop Kit Connections

11.1.9 Remote Reset Feature

The remote reset switch provides generator set resetting after a fault shutdown at a remote location. See Figure 11-15 and Figure 11-16 for user-supplied switch connection.

Press and hold the switch for 2–3 seconds and release to reset the generator set controller.

11.1.10 Remote Serial Annunciator (RSA III)

Adapted from Instruction TT-1625 9/14b.

The following information summarizes the setup items when installing the remote serial annunciator. Refer to the RSA installation instructions TT-1625 for operation and function.

RSA III Features and Connections

RSA III is an annunciator panel offered in several kit configurations to support Kohler power equipment. The RSA III is a remote serial annunciator that monitors the condition of the generator set and/or ATS from a remote location. The RSA III alerts the operator through visual and audible signals using LED indication and a horn. An alarm silence and lamp test switch are included.

An RSA III annunciator can be used for a single generator set (Figure 11-17) or with a combination of a generator set and automatic transfer switch(es) (Figure 11-18 or Figure 11-19). In systems using more than a single RSA III, one must be designated as the master device to broadcast to additional RSA III annunciators, designated as slave devices. Up to five RSA III slave devices can be used with an RSA III master device. All RSA III annunciators are factory set as the master device, but can be changed to a slave device using a PC and SiteTech™ software that connects to the RSA III front panel via a universal serial bus (USB) connection.

The RSA II can be connected with the RSA III provided that the master remote annunciator is an RSA III.

The RSA III meets NFPA 110, Level 1 (2005) applications that require remote controls and alarms be powered by a storage battery such as the engine starting battery. AC adaptor kit GM62466-KP1 is available when NFPA is not required.

See Section 11.2, Accessory Connections, for terminal identifications.

A PC with SiteTech™ software is required to make the RSA III functional. Use your SecurID to access KOHLERnet, click on the TechTools button, and follow the instructions to download the files. See SiteTech™ Software Settings and refer to TP-6701 SiteTech™ Software Operation Manual for more information.

If a fault occurs, the RSA III horn activates and the corresponding LED illuminates. The following paragraphs describe specific features of the RSA III.

If the RSA III is used with an Ethernet communication network, order Modbus® Ethernet converter GM41143-KP2 and refer to TT-1405 Converters,

Modbus® is a registered trademark of Schneider Electric.

Connections, and Controller Setup for Network Communication for system installation.

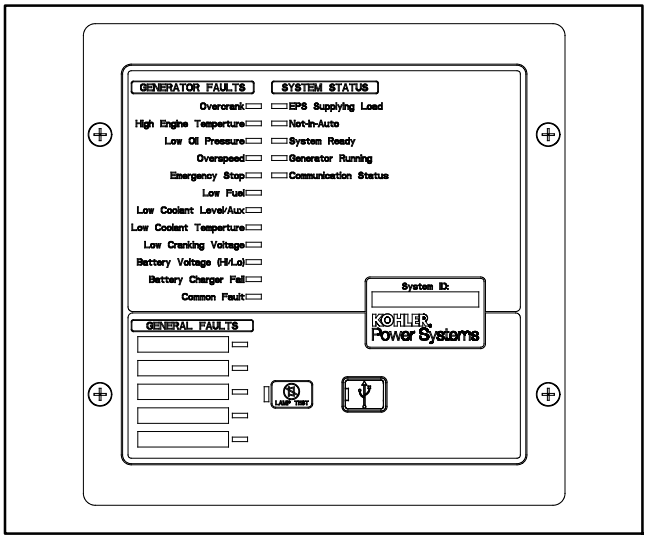

Figure 11-17 Remote Serial Annunciator (RSA III)

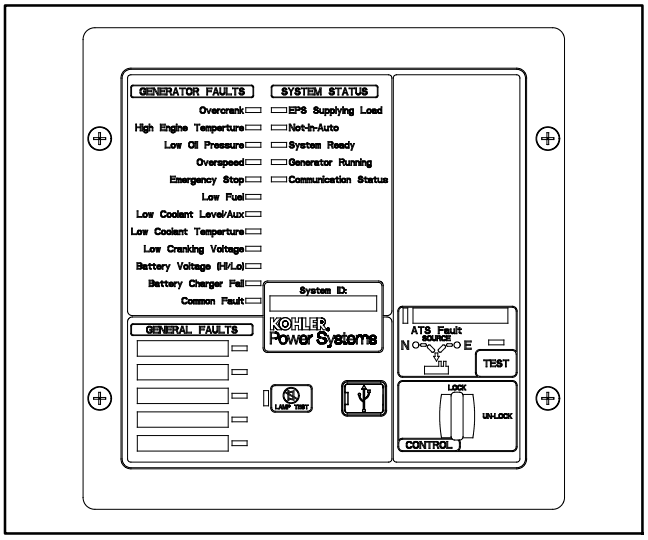

Figure 11-18 RSA III with Single ATS Control

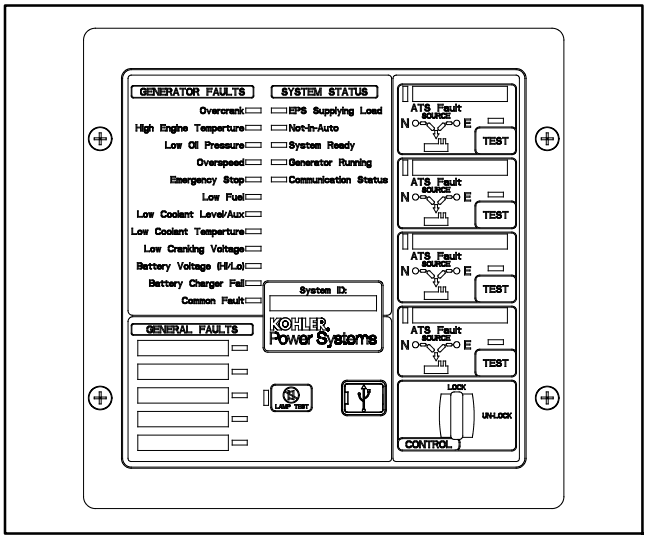

Figure 11-19 RSA III with Four ATS Controls

If there is only one RSA III, it is the master. If several RSA III are installed, choose either the RSA III closest to the generator set or determine which RSA III is more practical for use as a master and use a daisy chain wiring configuration for the remaining RSAs. The RSA III connected to the controller MUST be assigned as the RSA III master.

Note: When an RSA III is installed into a system with existing older RSAs, the RSA III must be configured as the master.

Note: Should any communication issues occur when adding RSA III slaves and/or transfer switches to the system, be sure to power down the RSA III master and then power up the RSA III master so that the RSA III master can recognize the changes.

Use the SiteTech™ software to select either that the generator set controller activates EPS Supplying Load LED or the transfer switch activates LED or local EPS supplying load.

Use the SiteTech™ software to select the high speed mode for direct connection to the DEC 6000 controller. Select lower speed for network connection with the Modbus®/ Ethernet converter. The lower speed allows network functionality reducing loss of communication faults.

Terminating Resistor and Wiring

For communication between the controller and RSA III master, see Figure 11-20. For communication between RSA III Master and RSA III Slave, see Figure 11-21. Place the terminating resistor on the last RSA III slave in the daisy chain connection.

Note: When using RS-485 communication cable, connect the “shield” wire at either end but not at both ends.

11.1.11 Shunt-Trip Line Circuit Breaker

A shunt-trip line circuit breaker provides a 12- or 24-DC volt solenoid within the line circuit breaker case that can energize the trip mechanism. This feature allows the circuit breaker to be tripped by a customer-selected fault such as alternator overload, overspeed, overvoltage, or defined common fault. Connection requires a shunt-trip wiring kit and a dry contact kit. See Figure 11-23.

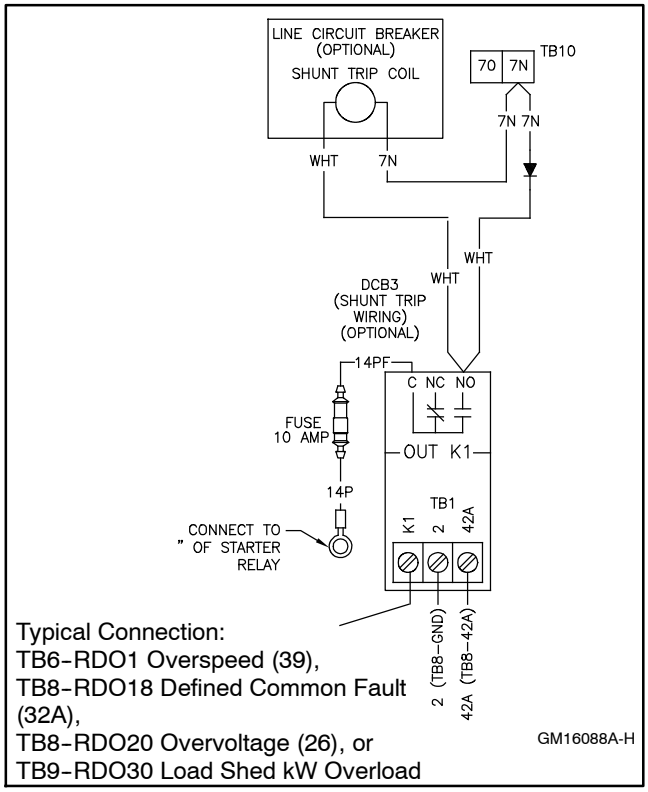

Figure 11-23 Shunt-Trip Line Circuit Breaker and Shunt-Trip Wiring Kit Connections

11.1.12 Single-Relay Dry Contact Kit

The single-relay dry contact kit provides normally open and normally closed contacts in a form C configuration to activate warning devices and other user- provided accessories allowing remote monitoring of the generator set. Typically, lamps, audible alarms, or other devices signal faults or status conditions. Connect any controller fault output to the single-relay dry contact kit.

A total of three dry contact kits may connect to a single controller output. See Figure 11-24 and Figure 11-25. See Section 11.2, Accessory Connections, for terminal identifications.

11.1.13 Ten-Relay Dry Contact Kit

The ten-relay dry contact kit provides normally open and normally closed contacts in a form C configuration to activate warning devices and other user-provided accessories allowing remote monitoring of the generator set. Connect any controller fault output to the ten-relay dry contact kit. Typically, lamps, audible alarms, or other devices signal the fault conditions.

Refer to Figure 11-26 for an internal view of the contact kit. See Figure 11-27 for electrical connections. See Section 11.2, Accessory Connections, for terminal identifications.

11.1.14 Twenty-Relay Dry Contact Kit

The twenty-relay dry contact kit provides normally open and normally closed contacts in a form C configuration to activate warning devices and other user-provided accessories allowing remote monitoring of the generator set. Typically, lamps, audible alarms, or other devices signal faults or status conditions. Connect any generator set fault output to the dry contact kit.

Refer to Figure 11-28 for an internal view of the contact kit. See Figure 11-29 for electrical connections. See Section 11.2, Accessory Connections, for terminal identifications.

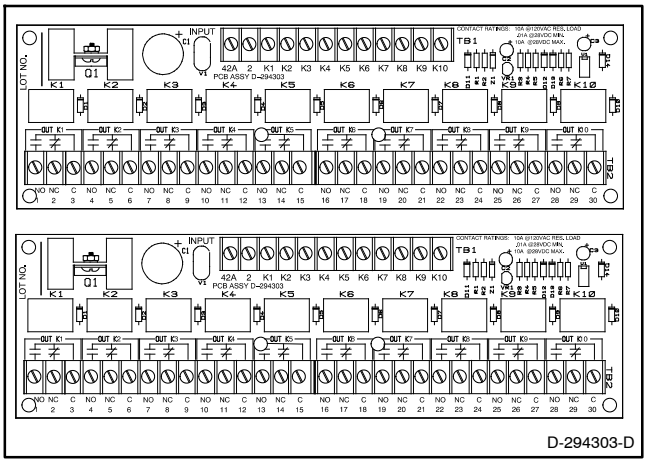

Figure 11-28 Twenty-Relay Dry Contact Kits

11.2 Accessory Connections

The controller contains circuit boards equipped with terminal strip(s) for use in connecting accessories. Connect accessories to either the controller customer connection terminal strip or a dry contact kit. Connect the dry contact kit(s) to the controller customer connection terminal strip. Connect alarms, battery chargers, remote switches, and other accessories to the dry contact kit relay(s).

For specific information on accessory connections, refer to the accessory wiring diagrams in the wiring diagram manual and the instruction sheet accompanying the kit. See Figure 11-30 and Figure 11-31 for controller interconnection circuit board connections. See Figure 11-32 and Figure 11-33 for controller (customer) connection terminal strip connections. See Appendix G, Wiring Diagrams for accessory connection wiring diagrams.

This section provides information about changes and adjustments when the system involves remote starting/control systems, voltage regulation, and paralleling generator set applications. Use the respective switchgear literature as supplied with the unit. Some of the items mentioned are available generator set accessories.

Before installing the generator set, provide for electrical connections through conduit to the transfer switch and other accessories for the generator set. Carefully install the selected generator set accessories. Route wiring to the generator set through flexible connections. Comply with all applicable codes when installing a wiring system.

See Section 7, Electrical System for additional wiring information.

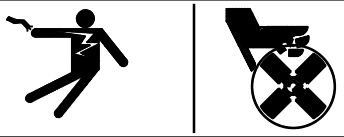
⚠ WARNING

Accidental starting.
Can cause severe injury or death.

Disconnect the battery cables before working on the generator set. Remove the negative (-) lead first when disconnecting the battery. Reconnect the negative (-) lead last when reconnecting the battery.

Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) Move the generator set master switch to the OFF position. (2) Disconnect the power to the battery charger. (3) Remove the battery cables, negative (-) lead first. Reconnect the negative (-) lead last when reconnecting the battery. Follow these precautions to prevent starting of the generator set by an automatic transfer switch, remote start/stop switch, or engine start command from a remote computer.

(Decision-Maker® 3+ and 550 Controllers)



Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) Press the generator set off/reset button to shut down the generator set. (2) Disconnect the power to the battery charger, if equipped. (3) Remove the battery cables, negative (-) lead first. Reconnect the negative (-) lead last when reconnecting the battery. Follow these precautions to prevent the starting of the generator set by the remote start/stop switch.

(Decision-Maker® 3000, 3500, and 6000 Controllers)

Disabling the generator set. Accidental starting can cause severe injury or death. Before working on the generator set or equipment connected to the set, disable the generator set as follows: (1) If the controller is not already in the MAN (manual) mode, press the Controller Mode button and then press the MAN mode button. (2) If the generator set is running, press and hold the Manual–Stop button for at least 2 seconds to stop the generator set. (3) Press the Controller Mode button and then press the controller Off mode button. (4) Disconnect the power to the battery charger, if equipped. (5) Remove the battery cables, negative (-) lead first. Reconnect the negative (-) lead last when reconnecting the battery. Follow these precautions to prevent the starting of the generator set by the remote start/stop switch.

(Decision-Maker® 8000 Controller)

⚠ WARNING

Hazardous voltage. Moving parts.
Can cause severe injury or death.

Operate the generator set only when all guards and electrical enclosures are in place.

Short circuits. Hazardous voltage/current can cause severe injury or death. Short circuits can cause bodily injury and/or equipment damage**.** Do not contact electrical connections with tools or jewelry while making adjustments or repairs. Remove all jewelry before servicing the equipment.

12.1 Automatic Transfer Switches

A typical standby system has at least one automatic transfer switch connected to the generator set output to automatically transfer the electrical load to the generator set if the normal source fails. When normal power returns, the switch transfers the load back to the normal power source and then signals the generator set to stop.

The transfer switch uses a set of contacts to signal the engine/generator to start. When the normal source fails and the generator set master switch is in the AUTO position, the transfer switch contacts close to start the generator set.

The engine start terminals are usually located near the transfer switch contactor with an engine start decal identifying the terminals. Refer to the transfer switch decal, operation/installation manual, or wiring diagram manual to identify the engine start terminals prior to making connections.

Make connections to the transfer switch engine-start terminals and remote manual engine-start switch using wire run through conduit. Use separate conduits for engine-start leads, generator set load cables, battery charger leads, and remote annunciator wiring.

Use a minimum of 13 mm (0.5 in.) spacing between the conduit bushing and any uninsulated live parts in the ATS enclosure. All conduit openings in the ATS enclosure must be made such that no metal particles including drill chips contaminate the components in the ATS enclosure.

12.2 Decision-Maker® 550 Controller, Voltage Regulator and Paralleling Applications

The controller has a voltage regulation function that is internal to the processor.

See the Decision-Maker® 550 Controller Operation Manual for further details regarding voltage adjustment and paralleling operation setup.

12.3 Decision-Maker® 3000 Controller Voltage Regulator

The controller has a voltage regulation function that is internal to the processor.

See the Decision-Maker® 3000 Controller and SiteTech™ Operation Manuals for further details regarding voltage adjustment setup.

12.4 Decision-Maker® 3500 Controller Voltage Regulator

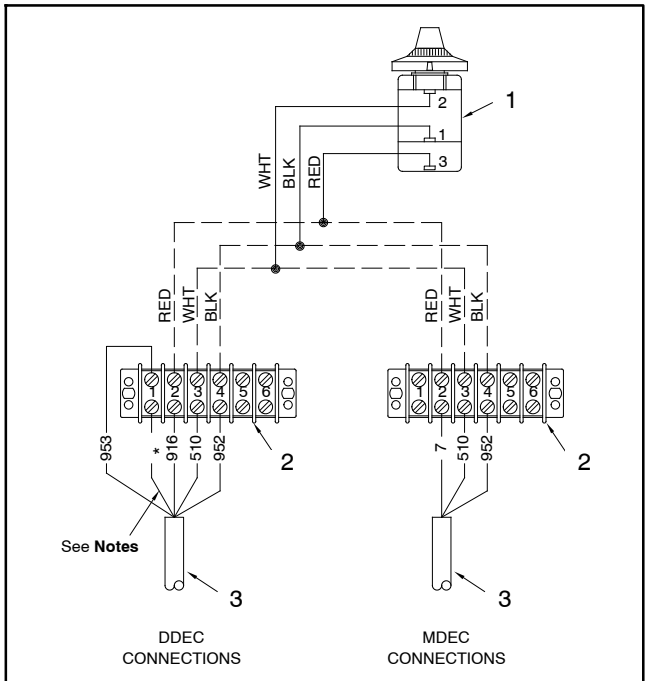
The controller has a voltage regulation function that is internal to the processor.

See the Decision-Maker® 3500 Controller and SiteTech™ Operation Manuals for further details regarding voltage adjustment setup.

12.5 Decision-Maker® 6000 Controller Voltage Regulator and Paralleling Applications

The controller has a voltage regulation function that is internal to the processor.

See the Decision-Maker® 6000 Controller, Decision-Maker® Paralleling (DPS), and SiteTech™ Operation Manuals for further details regarding voltage adjustment and paralleling operation setup.



12.6 Decision-Maker® 8000 Controller Voltage Regulator and Paralleling Applications

The generator set uses a Marathon® DVR® 2000EC voltage regulator.

See the Decision-Maker® 8000 Controller Operation Manual and TP-5579 Operation Manual, DVR® 2000 Voltage Regulator for further details regarding voltage adjustment and paralleling operation setup.

12.7 Remote Speed Adjustment

This kit provides remote engine speed adjustments with an approximate range of ±5% at 1800 rpm. This kit requires a generator set with an electronic governor. See Figure 12-1 and Figure 12-2.

Notes:

- Wire number is 542 on 2000/4000 series engine or 545 on 60 series engine (for DDEC connections only).
- Remove and tape wire 542 (545) when installing manual speed adjust kits.

To program the 550 controller, MDEC-equipped DDC/MTU engines only, use the following instructions. See the 550 controller operation manual for further information, if necessary.

1. Go to Menu 14—PROGRAMMING MODE to enable LOCAL programming.
2. Go to Menu 7—GENERATOR SYSTEM.
3. Press MENU Down ↓ Key to access ENABLE VSG (variable governor speed) data.
4. Press the YES Key.
5. Press the ENTER ← Key to confirm entry.
6. Verify ENABLE VSG code YES appears on the display.
7. Go to Menu 14—PROGRAMMING MODE to change to programming mode OFF.

12.8 Remote Voltage Adjustment

This kit provides the ability to fine adjust the generator output voltage from a remote location. The maximum recommended wire length from the potentiometer to the generator set is 15 ft. (4.6 m); 18-gauge twisted pair wire is recommended. See Figure 12-3 and Figure 12-4.

12.10 Voltage Regulator DVR 2000/ Remote Voltage Regulator Kit, 350 kW and Above

The DVR® 2000E is used with nonparalleling applications and the DVR® 2000EC is used when paralleling is required.

If the voltage configuration is changed, make adjustments to the DVR® 2000 voltage regulator at the voltage regulator. Remove the junction box cover to adjust the DVR® 2000 voltage regulator. See Figure 12-6, Figure 12-7, and TP-5579 Operation Manual, DVR® 2000 Voltage Regulator for more information.

Use Figure 12-7 for installation and troubleshooting of the electrical wiring system.

Appendix B Common Hardware Application Guidelines

Use the information below and on the following pages to identify proper fastening techniques when no specific reference for reassembly is made.

Bolt/Screw Length: When bolt/screw length is not given, use Figure 1 as a guide. As a general rule, a minimum length of one thread beyond the nut and a maximum length of 1/2 the bolt/screw diameter beyond the nut is the preferred method.

Washers and Nuts: Use split lock washers as a bolt locking device where specified. Use SAE flat washers with whiz nuts, spiralock nuts, or standard nuts and preloading (torque) of the bolt in all other applications.

See Appendix C, General Torque Specifications, and other torque specifications in the service literature.

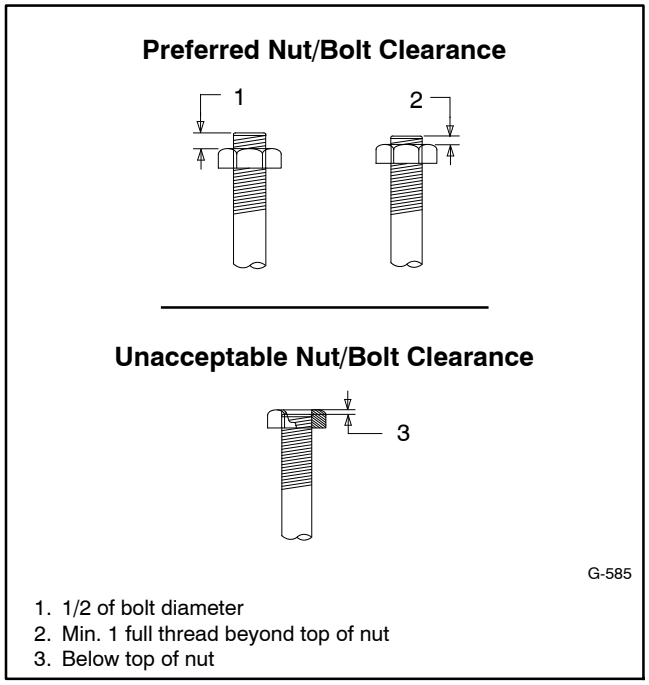

Figure 1 Acceptable Bolt Lengths

Steps for common hardware application:

1. Determine entry hole type: round or slotted.

2. Determine exit hole type: fixed female thread (weld nut), round, or slotted.

   For round and slotted exit holes, determine if hardware is greater than 1/2 inch in diameter, or 1/2 inch in diameter or less. Hardware that is *greater than 1/2 inch* in diameter takes a standard nut and SAE washer. Hardware *1/2 inch or less* in diameter can take a properly torqued whiz nut or spiralock nut. See Figure 2.

3. Follow these SAE washer rules after determining exit hole type:

   a. Always use a washer between hardware and a slot.

   b. Always use a washer under a nut (see 2 above for exception).

   c. Use a washer under a bolt when the female thread is fixed (weld nut).

4. Refer to Figure 2, which depicts the preceding hardware configuration possibilities.

Notes:

1. The torque values above are general guidelines. Always use the torque values specified in the service manuals and/or assembly drawings when they differ from the above torque values.
2. The torque values above are based on new plated threads. Increase torque values by 15% if non-plated threads are used.
3. Hardware threaded into aluminum must have either two diameters of thread engagement or a 30% or more reduction in the torque to prevent stripped threads.
4. Torque values are calculated as equivalent stress loading on American hardware with an approximate preload of 90% of the yield strength and a friction coefficient of 0.125.

Determining Propane Cylinder Quantity

Guide for Installing 100 lb. Cylinders

For continuous draws where temperatures may reach –18°C (0°F). Assume the vaporization rate of 100 lb. cylinder as approximately 50000 Btu/hr.

Number of cylinders/side = $\frac{\text{Total load in Btu}}{50000}$

Example:

Assume total load = 20000 Btu/hour.

Cylinders/side = $\frac{20000}{50000}$ = 4 cylinders/side

The chart in Figure 1 shows the vaporization rate of containers in terms of the temperature of the liquid and the wet surface area of the container. When the temperature is lower or if the container contains less liquid, the vaporization rate of the container is a lower value.

* These formulae allow for the temperature of the liquid to refrigerate to –29°C (–20°F), producing a temperature differential of –7°C (20°F) for the transfer of heat from the air to the container's *wetted* surface and then into the liquid. The vapor space area of the vessel is not considered since its effect is negligible.

† D=outside diameter in inches
L=overall length in inches
K=constant for percent volume of liquid in container.

OEM Engine and Drivetrain Warranty Registration

Why registering your OEM engine or drivetrain product is a really smart idea:[1]

Get faster service. Registering your engine or drivetrain product gives us the information we need to meet your service needs promptly and completely.

Protect your investment. You'll be kept up-to-date on engine or drivetrain product updates.

Extend your warranty. You'll be given the option to extend your coverage before your standard warranty term expires.

Stay informed. Be the first to know about new products and money-saving offers from John Deere.

NOTE: A mail-in registration form is located at the back of this manual.

You're Covered

When you buy a John Deere engine or drivetrain product you aren't just buying pistons and crankshafts and gear drives. You're buying the ability to get work done. Without downtime, without worries, and without hassles. And you're buying the assurance that if you do need help, a strong support network will be there — ready to step in.

Confidence. That's what John Deere engines, John Deere drivetrains, and John Deere Warranties are all about.

Long durations. Warranties designed to give you confidence in your engine or drivetrain product.

Worldwide support. Get service when and where you need it. John Deere has 4,000+ service locations worldwide.

Genuine John Deere parts and service. Authorized service outlets will use only new or remanufactured parts or components furnished by John Deere.

Warranty Duration

[1]Register your OEM engine or drivetrain product online and select an authorized John Deere service location. If available in your region, you'll receive information regarding new products and current money-saving offers from John Deere. Limit one money-saving offer per engine warranty registration. Not transferable. Not valid with any other offer. Offer ends 180 days from the date of issue. Some restrictions apply. See your John Deere service location for complete details.

RG24614 —UN—21OCT13

Scan this code to register your OEM engine online now and learn of current money-saving offers available to you.[1] You can also visit us directly at JohnDeere.com/warranty.

Equipment operators can't afford downtime or unexpected repairs. That's why we offer a 2-year/2,000-hour warranty, with unlimited hours in the first year, on our OEM industrial and marine engines. This warranty takes effect the date that the engine is delivered to the first retail purchaser. In addition, extended warranties are available under certain conditions. John Deere offers a variety of purchased warranties to extend the warranty period for your engine. You'll be given the option to extend your coverage before your standard warranty term expires. Be sure to register your engine or drivetrain product and take full advantage of the John Deere service and support network.

Obtaining Warranty Service

Warranty service must be requested through an authorized John Deere service outlet before the expiration of the warranty. Evidence of the engine's or drivetrain product's delivery date to the first retail purchaser must be presented when requesting warranty service. Authorized service outlets include:

- John Deere distributor
- John Deere OEM service dealer
- John Deere equipment dealer
- John Deere marine dealer

Worldwide Support Network

Visit JohnDeere.com/dealer to find the authorized engine or drivetrain service location nearest you. For complete warranty details visit JohnDeere.com/warrantystatements to view, download, or print the warranty statement for your engine or drivetrain product.

Foreword

READ THIS MANUAL carefully to learn how to operate and service your engine correctly. Failure to do so could result in personal injury or equipment damage.

THIS MANUAL SHOULD BE CONSIDERED a permanent part of your engine and should remain with the engine when you sell it.

MEASUREMENTS IN THIS MANUAL are given in both metric and customary U.S. unit equivalents. Use only correct replacement parts and fasteners. Metric and inch fasteners may require a specific metric or inch wrench.

RIGHT-HAND AND LEFT-HAND sides are determined by standing at the drive or flywheel end (rear) of the engine and facing toward the front of the engine.

WRITE ENGINE SERIAL NUMBERS and option codes in the spaces indicated in the Record Keeping section. Accurately record all the numbers. Your dealer also needs these numbers when you order parts. File the identification numbers in a secure place off the engine.

SETTING FUEL DELIVERY beyond published factory specifications or otherwise overpowering will result in loss of warranty protection for this engine.

CERTAIN ENGINE ACCESSORIES such as radiator, air cleaner, and instruments are optional equipment on John Deere OEM Engines. These accessories may be provided by the equipment manufacturer instead of John Deere. This operator's manual applies only to the engine and those options available through the John Deere distribution network.

NOTE: This operator's manual covers only engines provided to OEM (Original Equipment Manufacturers). For engines in Deere machines, refer to the machine operator's manual.

This manual covers primarily the PowerTech Plus 13.5 L (6135HF485) OEM engines. These engines meet emission standards for EPA Tier 3 and EU Stage III A. Other emission tiers of this engine size may be located in this manual based on the cover title.

Record Engine Serial Number

The engine serial number plate (C) is located on the left-hand side of engine block between intake manifold and starter motor.

Record all of the numbers and letters found on your engine serial number plate in the spaces provided below.

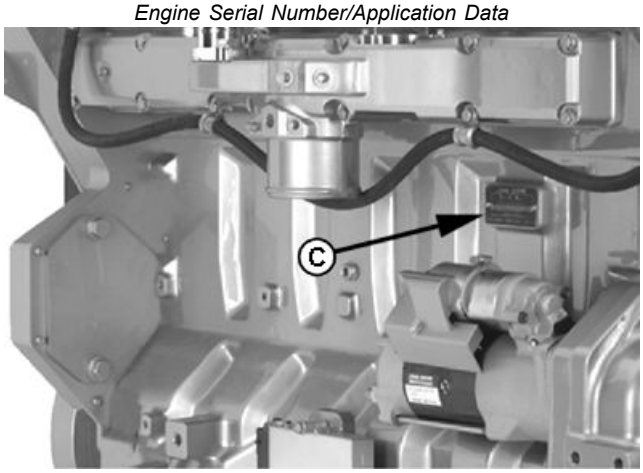
This information is very important for repair parts or warranty information.

Engine Serial Number (A)

_____

Engine Model Number (B)

_____



NOTE: On engine serial number (A) the 7th digit shows the emission level as follows:

- *"B" for non-certified engines*
- *"C" for Tier 1 / Stage I engines*
- *"G" for Tier 2 / Stage II engines*
- *"L" for Tier 3 / Stage IIIA engines*

Engine Option Codes

RG13880 —UN—06JUL05

Option Code Label

A—Base Engine Code

NOTE: Your engine option code label may not contain all option codes if an option has been added after the engine left the producing factory.

If option label is lost or destroyed, consult your servicing dealer or engine distributor selling the engine for a replacement.

In addition to the serial number plate, OEM engines have an engine option code label affixed to the valve cover. These codes indicate which of the engine options were installed on your engine at the factory. When in need of parts or service, furnish your authorized servicing dealer or engine distributor with these numbers.

The engine option code label includes an base engine code (A) (1665F, bold print in label above). Record this code along with option codes on following page.

The first two digits of each code identify a specific group, such as alternators. The last two digits of each code identify one specific option provided on your engine, such as a 24-volt, 60-amp alternator.

If an engine is ordered without a particular component, the last two digits of that functional group option code will be 99, 00, or XX. The list on the next page shows only the first two digits of the code numbers. For future reference, such as ordering repair parts, it is important to have these code numbers available. To ensure this availability, enter the third and fourth digits shown on your engine option code label in the spaces provided on the following page.

Emissions Label

Emissions Label

After Tier 4 standards take effect, engine manufacturers of emergency stationary engines that do not meet the standards for non-emergency engines must add to each such emergency engine a permanent label (such as the emission label as shown) which states that the engine is limited to stationary emergency use. On John Deere engines this is stated in the EPA emission label on each engine.

Fuel Requirements

Beginning 01 Oct 10, owners and operators of stationary engines that use diesel fuel must only use diesel fuel meeting the requirements of 40 CFR 80.510 (b), which requires that diesel fuel have a maximum sulfur content of 15 PPM and either a minimum cetane index of 40 or a maximum aromatic content of 35 volume percent.

Operation, Maintenance and Testing

The operation of emergency engines is limited to emergency operations and required maintenance and testing.

There is no time limit on the use of emergency stationary engines in emergency situations.

Maintenance and testing is limited to 100 hours per year. The EPA has also included a provision that allows anyone to petition the Administrator for additional hours, beyond the allowed 100 hours per year, if such additional hours should prove to be necessary for maintenance and testing reasons. The EPA will not require a petition for additional hours if the hours beyond 100 hours per year for maintenance and testing purposes are mandated by regulation such as State or Local requirements.

Understand Signal Words

TS187 —19—30SEP88

DANGER; The signal word DANGER indicates a hazardous situation which, if not avoided, will result in death or serious injury.

WARNING; The signal word WARNING indicates a hazardous situation which, if not avoided, could result in death or serious injury.

CAUTION; The signal word CAUTION indicates a hazardous situation which, if not avoided, could result in minor or moderate injury. CAUTION may also be used to alert against unsafe practices associated with events which could lead to personal injury.

A signal word—DANGER, WARNING, or CAUTION—is used with the safety-alert symbol. DANGER identifies the most serious hazards. DANGER or WARNING safety signs are located near specific hazards. General precautions are listed on CAUTION safety signs. CAUTION also calls attention to safety messages in this manual.

DX,SIGNAL -19-05OCT16-1/1

Recognize Safety Information

This is a safety-alert symbol. When you see this symbol on your machine or in this manual, be alert to the potential for personal injury.

Follow Safety Instructions

Carefully read all safety messages in this manual and on your machine safety signs. Keep safety signs in good condition. Replace missing or damaged safety signs. Be sure new equipment components and repair parts include the current safety signs. Replacement safety signs are available from your John Deere dealer.

There can be additional safety information contained on parts and components sourced from suppliers that is not reproduced in this operator's manual.

Learn how to operate the machine and how to use controls properly. Do not let anyone operate without instruction.

Keep your machine in proper working condition. Unauthorized modifications to the machine may impair the function and/or safety and affect machine life.

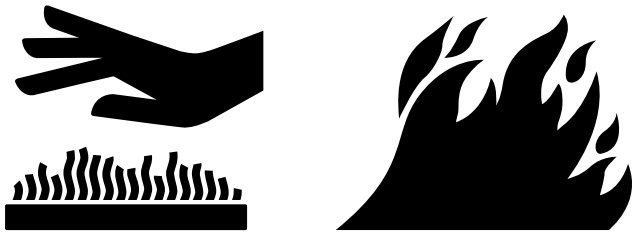
California Proposition 65 Warning



Diesel engine exhaust, some of its constituents, along with certain machine components contain or emit chemicals known to the State of California to cause cancer and birth defects or other reproductive harm. In addition, certain fluids contained in the machine and certain products of component wear contain or emit chemicals known to the State of California to cause cancer and birth defects or other reproductive harm.

Avoid Hot Exhaust

Servicing machine or attachments with engine running can result in serious personal injury. Avoid exposure and skin contact with hot exhaust gases and components.

Exhaust parts and streams become very hot during operation. Exhaust gases and components reach temperatures hot enough to burn people, ignite, or melt common materials.

Work In Ventilated Area

Engine exhaust fumes can cause sickness or death. If it is necessary to run an engine in an enclosed area, remove the exhaust fumes from the area with an exhaust pipe extension.

If you do not have an exhaust pipe extension, open the doors and get outside air into the area.

Decommissioning — Proper Recycling and Disposal of Fluids and Components

Safety and environmental stewardship measures must be taken into account when decommissioning a machine and/or component. These measures include the following:

- Use appropriate tools and personal protective equipment such as clothing, gloves, face shields or glasses, during the removal or handling of objects and materials.
- Follow instructions for specialized components.
- Release stored energy by lowering suspended machine elements, relaxing springs, disconnecting the battery or other electrical power, and releasing pressure in hydraulic components, accumulators, and other similar systems.
- Minimize exposure to components which may have residue from agricultural chemicals, such as fertilizers and pesticides. Handle and dispose of these components appropriately.
- Carefully drain engines, fuel tanks, radiators, hydraulic cylinders, reservoirs, and lines before recycling components. Use leak-proof containers when draining fluids. Do not use food or beverage containers.
- Do not pour waste fluids onto the ground, down a drain, or into any water source.
- Observe all national, state, and local laws, regulations, or ordinances governing the handling or disposal of waste fluids (example: oil, fuel, coolant, brake fluid);

TS1133 —UN—15APR13

filters; batteries; and, other substances or parts. Burning of flammable fluids or components in other than specially designed incinerators may be prohibited by law and could result in exposure to harmful fumes or ashes.

- Service and dispose of air conditioning systems appropriately. Government regulations may require a certified service center to recover and recycle air conditioning refrigerants which could damage the atmosphere if allowed to escape.
- Evaluate recycling options for tires, metal, plastic, glass, rubber, and electronic components which may be recyclable, in part or completely.
- Contact your local environmental or recycling center, or your John Deere dealer for information on the proper way to recycle or dispose of waste.

Prevent Machine Runaway

Avoid possible injury or death from machinery runaway.

Do not start engine by shorting across starter terminals. Machine will start in gear if normal circuitry is bypassed.

NEVER start engine while standing on ground. Start engine only from operator's seat, with transmission in neutral or park.

DX,BYPAS1 -19-29SEP98-1/1

Practice Safe Maintenance

Understand service procedure before doing work. Keep area clean and dry.

Never lubricate, service, or adjust machine while it is moving. Keep hands, feet , and clothing from power-driven parts. Disengage all power and operate controls to relieve pressure. Lower equipment to the ground. Stop the engine. Remove the key. Allow machine to cool.

Securely support any machine elements that must be raised for service work.

Keep all parts in good condition and properly installed. Fix damage immediately. Replace worn or broken parts. Remove any buildup of grease, oil, or debris.

On self-propelled equipment, disconnect battery ground cable (-) before making adjustments on electrical systems or welding on machine.

On towed implements, disconnect wiring harnesses from tractor before servicing electrical system components or welding on machine.

Support Machine Properly

Always lower the attachment or implement to the ground before you work on the machine. If the work requires that the machine or attachment be lifted, provide secure support for them. If left in a raised position, hydraulically supported devices can settle or leak down.

Do not support the machine on cinder blocks, hollow tiles, or props that may crumble under continuous load. Do not work under a machine that is supported solely by a jack. Follow recommended procedures in this manual.

When implements or attachments are used with a machine, always follow safety precautions listed in the implement or attachment operator's manual.

Remove Paint Before Welding or Heating

Avoid potentially toxic fumes and dust.

Hazardous fumes can be generated when paint is heated by welding, soldering, or using a torch.

Remove paint before heating:

- Remove paint a minimum of 100 mm (4 in.) from area to be affected by heating. If paint cannot be removed, wear an approved respirator before heating or welding.
- If you sand or grind paint, avoid breathing the dust. Wear an approved respirator.
- If you use solvent or paint stripper, remove stripper with soap and water before welding. Remove solvent or paint stripper containers and other flammable material from area. Allow fumes to disperse at least 15 minutes before welding or heating.

Do not use a chlorinated solvent in areas where welding will take place.

TS220 —UN—15APR13

Do all work in an area that is well ventilated to carry toxic fumes and dust away.

Dispose of paint and solvent properly.

DX,PAINT -19-24JUL02-1/1

Do Not Open High-Pressure Fuel System

High-pressure fluid remaining in fuel lines can cause serious injury. Do not disconnect or attempt repair of fuel lines, sensors, or any other components between the high-pressure fuel pump and nozzles on engines with High Pressure Common Rail (HPCR) fuel system.

Only technicians familiar with this type of system can perform repairs. (See your John Deere dealer.)

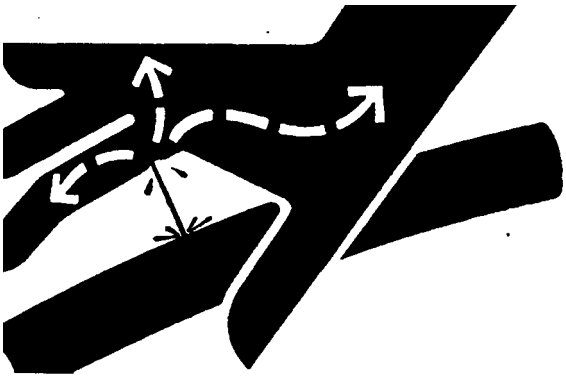
Avoid High-Pressure Fluids

Inspect hydraulic hoses periodically – at least once per year – for leakage, kinking, cuts, cracks, abrasion, blisters, corrosion, exposed wire braid or any other signs of wear or damage.



Replace worn or damaged hose assemblies immediately with John Deere approved replacement parts.

Escaping fluid under pressure can penetrate the skin causing serious injury.

Avoid the hazard by relieving pressure before disconnecting hydraulic or other lines. Tighten all connections before applying pressure.

Search for leaks with a piece of cardboard. Protect hands and body from high-pressure fluids.

If an accident occurs, see a doctor immediately. Any fluid injected into the skin must be surgically removed within a few hours or gangrene may result. Doctors unfamiliar with this type of injury should reference a knowledgeable medical source. Avoid Heating Near Pressurized Fluid Lines

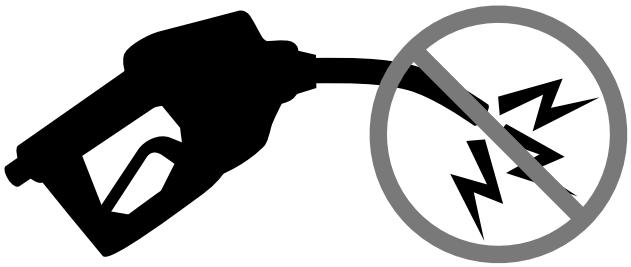
Flammable spray can be generated by heating near pressurized fluid lines, resulting in severe burns to yourself and bystanders. Do not heat by welding, soldering, or using a torch near pressurized fluid lines or other flammable materials. Pressurized lines can accidentally burst when heat goes beyond the immediate flame area.

TS953 —UN—15MAY90

DX,TORCH -19-10DEC04-1/1

Avoid Static Electricity Risk When Refueling

The removal of sulfur and other compounds in Ultra-Low Sulfur Diesel (ULSD) fuel decreases its conductivity and increases its ability to store a static charge.



Refineries may have treated the fuel with a static dissipating additive. However, there are many factors that can reduce the effectiveness of the additive over time.

Static charges can build up in ULSD fuel while it is flowing through fuel delivery systems. Static electricity discharge when combustible vapors are present could result in a fire or explosion.

Therefore, it is important to ensure that the entire system used to refuel your machine (fuel supply tank, transfer pump, transfer hose, nozzle, and others) is properly grounded and bonded. Consult with your fuel or fuel system supplier to ensure that the delivery system is in compliance with fueling standards for proper grounding and bonding practices.

Handle Fuel Safely—Avoid Fires

Handle fuel with care: it is highly flammable. Do not refuel the machine while smoking or when near open flame or sparks.

Always stop engine before refueling machine. Fill fuel tank outdoors.

Prevent fires by keeping machine clean of accumulated trash, grease, and debris. Always clean up spilled fuel.

Use only an approved fuel container for transporting flammable liquids.

Never fill fuel container in pickup truck with plastic bed liner. Always place fuel container on ground before refueling. Touch fuel container with fuel dispenser nozzle before removing can lid. Keep fuel dispenser nozzle in contact with fuel container inlet when filling.

TS202 —UN—23AUG88

Handle Starting Fluid Safely

Starting fluid is highly flammable.

Keep all sparks and flame away when using it. Keep starting fluid away from batteries and cables.

To prevent accidental discharge when storing the pressurized can, keep the cap on the container, and store in a cool, protected location.

Do not incinerate or puncture a starting fluid container.

Do not use starting fluid on an engine equipped with glow plugs or an air intake heater.

Handling Batteries Safely

Battery gas can explode. Keep sparks and flames away from batteries. Use a flashlight to check battery electrolyte level.

Never check battery charge by placing a metal object across the posts. Use a voltmeter or hydrometer.

Always remove grounded (-) battery clamp first and replace grounded clamp last.

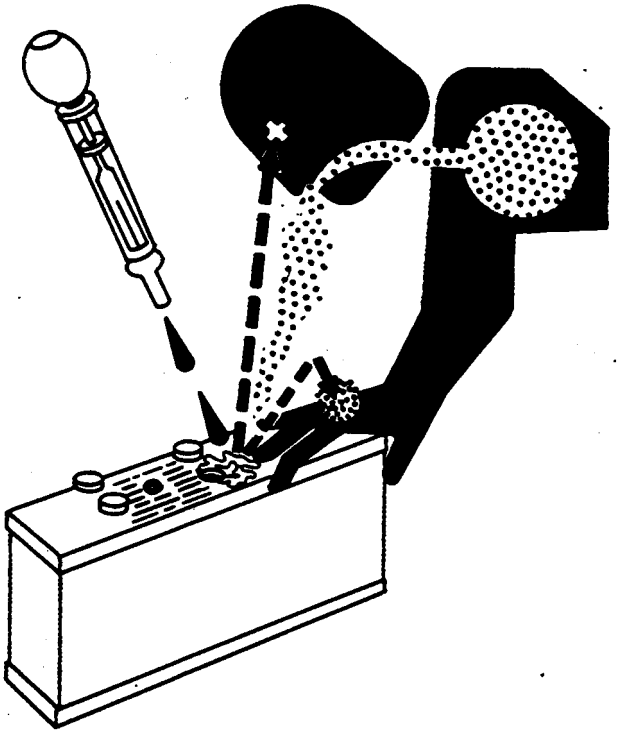
Sulfuric acid in battery electrolyte is poisonous and strong enough to burn skin, eat holes in clothing, and cause blindness if splashed into eyes.

Avoid hazards by:

- Filling batteries in a well-ventilated area
- Wearing eye protection and rubber gloves
- Avoiding use of air pressure to clean batteries
- Avoiding breathing fumes when electrolyte is added
- Avoiding spilling or dripping electrolyte
- Using correct battery booster or charger procedure.

If acid is spilled on skin or in eyes:

1. Flush skin with water.
2. Apply baking soda or lime to help neutralize the acid.
3. Flush eyes with water for 15—30 minutes. Get medical attention immediately.



If acid is swallowed:

1. Do not induce vomiting.
2. Drink large amounts of water or milk, but do not exceed 2 L (2 qt.).
3. Get medical attention immediately.

WARNING: Battery posts, terminals, and related accessories contain lead and lead compounds, chemicals known to the State of California to cause cancer and reproductive harm. **Wash hands after handling.**

Diesel Fuel

Consult your local fuel distributor for properties of the diesel fuel available in your area.

In general, diesel fuels are blended to satisfy the low temperature requirements of the geographical area in which they are marketed.

Diesel fuels specified to EN 590 or ASTM D975 are recommended. Renewable diesel fuel produced by hydrotreating animal fats and vegetable oils is basically identical to petroleum diesel fuel. Renewable diesel that meets EN 590, ASTM D975, or EN 15940 is acceptable for use at all percentage mixture levels.

Required Fuel Properties

In all cases, the fuel shall meet the following properties:

Cetane number of 40 minimum. Cetane number greater than 47 is preferred, especially for temperatures below –20 °C (–4 °F) or elevations above 1675 m (5500 ft.).

Cold Filter Plugging Point (CFPP) should be at least 5 °C (9 °F) below the expected lowest temperature or **Cloud Point** below the expected lowest ambient temperature.

Fuel lubricity should pass a maximum scar diameter of 0.52 mm as measured by ASTM D6079 or ISO 12156-1. A maximum scar diameter of 0.45 mm is preferred.

Diesel fuel quality and sulfur content must comply with all existing emissions regulations for the area in which the engine operates. DO NOT use diesel fuel with sulfur content greater than 10 000 mg/kg (10 000 ppm).

E-Diesel fuel

DO NOT use E-Diesel (Diesel fuel and ethanol blend). Use of E-Diesel fuel in any John Deere machine may void the machine warranty.

CAUTION: Avoid severe injury or death due to the fire and explosion risk from using E-Diesel fuel.

Sulfur content for Interim Tier 4, Final Tier 4, Stage III B, and Stage IV Engines

- Use ONLY ultra low sulfur diesel (ULSD) fuel with a maximum of 15 mg/kg (15 ppm) sulfur content.

Sulfur Content for Tier 3 and Stage III A Engines

- Use of diesel fuel with sulfur content less than 1000 mg/kg (1000 ppm) is RECOMMENDED.
- Use of diesel fuel with sulfur content 1000—2000 mg/kg (1000—2000 ppm) REDUCES the oil and filter change interval.
- BEFORE using diesel fuel with sulfur content greater than 2000 mg/kg (2000 ppm), contact your John Deere dealer.

Sulfur Content for Tier 2 and Stage II Engines

- Use of diesel fuel with sulfur content less than 2000 mg/kg (2000 ppm) is RECOMMENDED.
- Use of diesel fuel with sulfur content 2000—5000 mg/kg (2000—5000 ppm) REDUCES the oil and filter change interval.
- BEFORE using diesel fuel with sulfur content greater than 5000 mg/kg (5000 ppm), contact your John Deere dealer.

Sulfur Content for Other Engines

- Use of diesel fuel with sulfur content less than 5000 mg/kg (5000 ppm) is RECOMMENDED.
- Use of diesel fuel with sulfur content greater than 5000 mg/kg (5000 ppm) REDUCES the oil and filter change interval.

IMPORTANT: Do not mix used diesel engine oil or any other type of lubricating oil with diesel fuel.

Improper fuel additive usage may cause damage on fuel injection equipment of diesel engines.

DX,FUEL1 -19-13JAN16-1/1

Supplemental Diesel Fuel Additives

Diesel fuel can be the source of performance or other operational problems for many reasons. Some causes include poor lubricity, contaminants, low cetane number, and a variety of properties that cause fuel system deposits. These and others are referenced in other sections of this Operator's Manual.

To optimize engine performance and reliability, closely follow recommendations on fuel quality, storage, and handling, which are found elsewhere in this Operator's Manual.

To further aid in maintaining performance and reliability of the engine's fuel system, John Deere has developed a family of fuel additive products for most global markets. The primary products include Fuel-Protect Diesel Fuel Conditioner (full feature conditioner in winter and summer formulas) and Fuel-Protect Keep Clean (fuel injector deposit removal and prevention). Availability of these and other products varies by market. See your local John Deere dealer for availability and additional information about fuel additives that might be right for your needs.

DX,FUEL13 -19-07FEB14-1/1

Lubricity of Diesel Fuel

Most diesel fuels manufactured in the United States, Canada, and the European Union have adequate lubricity to ensure proper operation and durability of fuel injection system components. However, diesel fuels manufactured in some areas of the world may lack the necessary lubricity.

IMPORTANT: Make sure the diesel fuel used in your machine demonstrates good lubricity characteristics.

Fuel lubricity should pass a maximum scar diameter of 0.52 mm as measured by ASTM D6079 or ISO 12156-1. A maximum scar diameter of 0.45 mm is preferred.

If fuel of low or unknown lubricity is used, add John Deere Fuel-Protect Diesel Fuel Conditioner (or equivalent) at the specified concentration.

Lubricity of BioDiesel Fuel

Fuel lubricity can improve significantly with BioDiesel blends up to B20 (20% BioDiesel). Further increase in lubricity is limited for BioDiesel blends greater than B20.

DX,FUEL5 -19-07FEB14-1/1

Handling and Storing Diesel Fuel

CAUTION: Reduce the risk of fire. Handle fuel carefully. DO NOT fill the fuel tank when engine is running. DO NOT smoke while you fill the fuel tank or service the fuel system.

Fill the fuel tank at the end of each day's operation to prevent water condensation and freezing during cold weather.

Keep all storage tanks as full as practical to minimize condensation.

Ensure that all fuel tank caps and covers are installed properly to prevent moisture from entering. Monitor water content of the fuel regularly.

When using biodiesel fuel, the fuel filter may require more frequent replacement due to premature plugging.

Check engine oil level daily prior to starting engine. A rising oil level may indicate fuel dilution of the engine oil.

IMPORTANT: The fuel tank is vented through the filler cap. If a new filler cap is required, always replace it with an original vented cap.

When fuel is stored for an extended period or if there is a slow turnover of fuel, add a fuel conditioner to stabilize the fuel and prevent water condensation. Contact your fuel supplier or John Deere dealer for recommendations.

DX,FUEL4 -19-15FEB13-1/1

BioDiesel Fuel

BioDiesel fuel is comprised of mono-alkyl esters of long chain fatty acids derived from vegetable oils or animal fats. BioDiesel blends are BioDiesel mixed with petroleum diesel fuel on a volume basis.

Before using fuel containing BioDiesel, review the BioDiesel Use Requirements and Recommendations in this Operator's Manual.

Environmental laws and regulations can encourage or prohibit the use of biofuels. Operators should consult with appropriate governmental authorities prior to using biofuels.

All John Deere Engines with Exhaust Filter (Released 2011 and After)

While 5% blends (B5) are preferred, BioDiesel concentrations up to a 20% blend (B20) in petroleum diesel fuel can be used. BioDiesel blends up to B20 can be used ONLY if the BioDiesel (100% BioDiesel or B100) meets ASTM D6751, EN 14214, or equivalent specification. Expect a 2% reduction in power and a 3% reduction in fuel economy when using B20.

BioDiesel concentrations above B20 can harm the engine's emission control systems and should not be used. Risks include, but are not limited to, more frequent stationary regeneration, soot accumulation, and increased intervals for ash removal.

John Deere approved fuel conditioners, which contain detergent and dispersant additives, are required when using BioDiesel blends from B10—B20, and are recommended when using lower BioDiesel blends.

All John Deere Engines Excluding Exhaust Filter (Primarily Released Prior to 2012)

While 5% blends (B5) are preferred, BioDiesel concentrations up to a 20% blend (B20) in petroleum diesel fuel can be used. BioDiesel blends up to B20 can be used ONLY if the BioDiesel (100% BioDiesel or B100) meets ASTM D6751, EN 14214, or equivalent specification. Expect a 2% reduction in power and a 3% reduction in fuel economy when using B20.

These John Deere engines can operate on BioDiesel blends above B20 (up to 100% BioDiesel). Operate at levels above B20 ONLY if the BioDiesel is permitted by law and meets the EN 14214 specification (primarily available in Europe). Engines operating on BioDiesel blends above B20 might not fully comply with or be permitted by all applicable emissions regulations. Expect up to a 12% reduction in power and an 18% reduction in fuel economy when using 100% BioDiesel.

John Deere approved fuel conditioners, which contain detergent and dispersant additives, are required when using BioDiesel blends from B10—B20, and are recommended when using lower BioDiesel blends.

BioDiesel Use Requirements and Recommendations

The petroleum diesel portion of all BioDiesel blends must meet the requirements of ASTM D975 (US) or EN 590 (EU) commercial standard.

BioDiesel users in the U.S. are strongly encouraged to purchase BioDiesel blends from a BQ-9000 Certified Marketer and sourced from a BQ-9000 Accredited Producer (as certified by the National BioDiesel Board). Certified Marketers and Accredited Producers can be found at the following website: http://www.bq9000.org.

BioDiesel contains residual ash. Ash levels exceeding the maximums allowed in either ASTM D6751 or EN14214 can result in more rapid ash loading and require more frequent cleaning of the Exhaust Filter (if present).

The fuel filter can require more frequent replacement, when using BioDiesel fuel, particularly if switching from diesel. Check engine oil level daily prior to starting engine. A rising oil level can indicate fuel dilution of the engine oil. BioDiesel blends up to B20 must be used within 90 days of the date of BioDiesel manufacture. BioDiesel blends above B20 must be used within 45 days from the date of BioDiesel manufacture.

When using BioDiesel blends up to B20, the following must be considered:

- Cold-weather flow degradation
- Stability and storage issues (moisture absorption, microbial growth)
- Possible filter restriction and plugging (usually a problem when first switching to BioDiesel on used engines)
- Possible fuel leakage through seals and hoses (primarily an issue with older engines)
- Possible reduction of service life of engine components

Request a certificate of analysis from your fuel distributor to ensure that the fuel is compliant with the specifications provided in this Operator's Manual.

Consult your John Deere dealer for approved fuel conditioners to improve storage and performance with BioDiesel fuels.

The following must also be considered if using BioDiesel blends above B20:

- Possible coking or blocked injector nozzles, resulting in power loss and engine misfire if John Deere approved fuel conditioners are not used
- Possible crankcase oil dilution (requiring more frequent oil changes)
- Possible lacquering or seizure of internal components
- Possible formation of sludge and sediments
- Possible thermal oxidation of fuel at elevated temperatures
- Possible compatibility issues with other materials (including copper, lead, zinc, tin, brass, and bronze) used in fuel handling equipment

Continued on next page

DX,FUEL7 -19-15MAY13-1/2

- Possible reduction in water separator efficiency
- Possible damage to paint if exposed to BioDiesel
- Possible corrosion of fuel injection equipment
- Possible elastomeric seal and gasket material degradation (primarily an issue with older engines)
- Possible high acid levels within fuel system
- Because BioDiesel blends above B20 contain more ash, using blends above B20 can result in more rapid ash loading and require more frequent cleaning of the Exhaust Filter (if present)

IMPORTANT: Raw pressed vegetable oils are NOT acceptable for use as fuel in any concentration in John Deere engines. Their use could cause engine failure.

DX,FUEL7 -19-15MAY13-2/2

Testing Diesel Fuel

A fuel analysis program can help to monitor the quality of diesel fuel. The fuel analysis can provide critical data such as cetane number, fuel type, sulfur content, water content, appearance, suitability for cold weather operations, bacteria, cloud point, acid number, particulate contamination, and whether the fuel meets specification.

Contact your John Deere dealer for more information on diesel fuel analysis.

DX,FUEL6 -19-14APR11-1/1

Fuel Filters

The importance of fuel filtration cannot be overemphasized with modern fuel systems. The combination of increasingly restrictive emission regulations and more efficient engines requires fuel system to operate at much higher pressures. Higher pressures can only be achieved using fuel injection components with very close tolerances. These close manufacturing tolerances have significantly reduced capacities for debris and water.

John Deere brand fuel filters have been designed and produced specifically for John Deere engines.

To protect the engine from debris and water, always change engine fuel filters as specified in this manual.

DX,FILT2 -19-14APR11-1/1

Minimizing the Effect of Cold Weather on Diesel Engines

John Deere diesel engines are designed to operate effectively in cold weather.

However, for effective starting and cold-weather operation, a little extra care is necessary. The following information outlines steps that can minimize the effect that cold weather may have on starting and operation of your engine. See your John Deere dealer for additional information and local availability of cold-weather aids.

Use Winter Grade Fuel

When temperatures fall below 0 °C (32 °F), winter grade fuel (No. 1-D in North America) is best suited for cold-weather operation. Winter grade fuel has a lower cloud point and a lower pour point.

Cloud point is the temperature at which wax begins to form in the fuel. This wax causes fuel filters to plug. **Pour point** is the lowest temperature at which movement of the fuel is observed.

NOTE: On average, winter grade diesel fuel has a lower Btu (heat content) rating. Using winter grade fuel may reduce power and fuel efficiency, but should not cause any other engine performance effects. Check the grade of fuel being used before troubleshooting for low-power complaints in cold-weather operation.

Air Intake Heater

An air intake heater is an available option for some engines to aid cold weather starting.

Ether

An ether port on the intake is available to aid cold weather starting.

CAUTION: Ether is highly flammable. Do not use ether when starting an engine equipped with glow plugs or an air intake heater.

Coolant Heater

An engine block heater (coolant heater) is an available option to aid cold weather starting.

Seasonal Viscosity Oil and Proper Coolant Concentration

Use seasonal grade viscosity engine oil based on the expected air temperature range between oil changes and a proper concentration of low silicate antifreeze as recommended. (See DIESEL ENGINE OIL and ENGINE COOLANT requirements in this section.)

Diesel Fuel Flow Additive

Use John Deere Fuel-Protect Diesel Fuel Conditioner (winter formula), which contains anti-gel chemistry, or equivalent fuel conditioner to treat non-winter grade fuel (No. 2-D in North America) during the cold-weather season. This generally extends operability to about 10 °C (18 °F) below the fuel cloud point. For operability at even lower temperatures, use winter grade fuel.

IMPORTANT: Treat fuel when outside temperature drops below 0 °C (32 °F). For best results, use with untreated fuel. Follow all recommended instructions on label.

BioDiesel

When operating with BioDiesel blends, wax formation can occur at warmer temperatures. Begin using John Deere Fuel-Protect Diesel Fuel Conditioner (winter formula) at 5 °C (41 °F) to treat BioDiesel fuels during the cold-weather season. Use B5 or lower blends at temperatures below 0 °C (32 °F). Use only winter grade petroleum diesel fuel at temperatures below -10 °C (14 °F).

Winterfronts

Use of fabric, cardboard, or solid winterfronts is not recommended with any John Deere engine. Their use can result in excessive engine coolant, oil, and charge air temperatures. This can lead to reduced engine life, loss of power and poor fuel economy. Winterfronts may also put abnormal stress on fan and fan drive components potentially causing premature failures.

If winterfronts are used, they should never totally close off the grill frontal area. Approximately 25% area in the center of the grill should remain open at all times. At no time should the air blockage device be applied directly to the radiator core.

Radiator Shutters

If equipped with a thermostatically controlled radiator shutter system, this system should be regulated in such a way that the shutters are completely open by the time the coolant reaches 93 °C (200 °F) to prevent excessive intake manifold temperatures. Manually controlled systems are not recommended.

If air-to-air aftercooling is used, the shutters must be completely open by the time the intake manifold air temperature reaches the maximum allowable temperature out of the charge air cooler.

For more information, see your John Deere dealer.

Diesel Engine Break-In Oil — Non-Emissions Certified and Certified Tier 1, Tier 2, Tier 3, Stage I, Stage II, and Stage III

New engines are filled at the factory with either John Deere Break-In™ or John Deere Break-In Plus™ Engine Oil. During the break-in period, add John Deere Break-In™ or Break-In Plus™ Engine Oil, respectively, as needed to maintain the specified oil level.

Operate the engine under various conditions, particularly heavy loads with minimal idling, to help seat engine components properly.

If John Deere Break-In™ Engine Oil is used during the initial operation of a new or rebuilt engine, change the oil and filter at a maximum of 100 hours.

If John Deere Break-In Plus™ Engine Oil is used, change the oil and filter at a minimum of 100 hours and a maximum equal to the interval specified for John Deere Plus-50™ II or Plus-50™ oil.

After engine overhaul, fill the engine with either John Deere Break-In™ or Break-In Plus™ Engine Oil.

If John Deere Break-In™ or Break-In Plus™ Engine Oil is not available, use an SAE 10W-30 viscosity grade diesel engine oil meeting one of the following and change the oil and filter at a maximum of 100 hours of operation:

- API Service Classification CE
- API Service Classification CD
- API Service Classification CC
- ACEA Oil Sequence E2
- ACEA Oil Sequence E1

IMPORTANT: Do not use Plus-50™ II, Plus-50™, or engine oils meeting any of the following for the initial break-in of a new or rebuilt engine:

API CK-4	**ACEA E9**
API CJ-4	**ACEA E7**
API CI-4 PLUS	**ACEA E6**
API CI-4	**ACEA E5**
API CH-4	**ACEA E4**
API CG-4	**ACEA E3**
API CF-4	
API CF-2	
API CF	

These oils do not allow the engine to break in properly.

John Deere Break-In Plus™ Engine Oil can be used for all John Deere diesel engines at all emission certification levels.

After the break-in period, use John Deere Plus-50™ II, John Deere Plus-50™, or other diesel engine oil as recommended in this manual.

Break-In Plus is a trademark of Deere & Company
Plus-50 is a trademark of Deere & Company.

DX,ENOIL4 -19-02NOV16-1/1

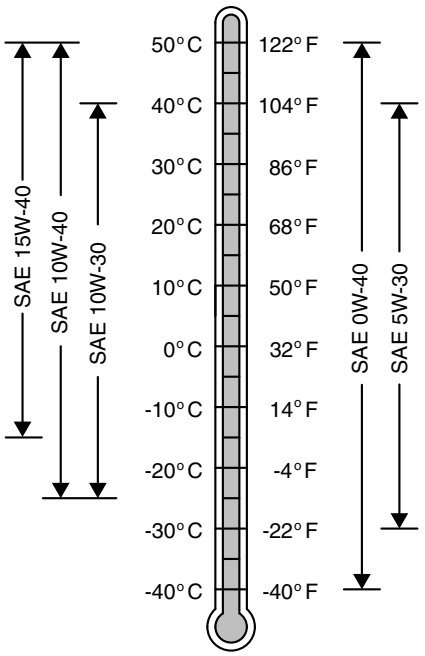
Diesel Engine Oil — Tier 3 and Stage III

Use oil viscosity based on the expected air temperature range during the period between oil changes.

John Deere Plus-50™ II oil is preferred.

John Deere Plus-50™ is also recommended.

Other oils may be used if they meet one or more of the following:



- John Deere Torq-Gard™
- API Service Category CK-4
- API Service Category CJ-4
- API Service Category CI-4 PLUS
- API Service Category CI-4
- ACEA Oil Sequence E9
- ACEA Oil Sequence E7
- ACEA Oil Sequence E6
- ACEA Oil Sequence E5
- ACEA Oil Sequence E4

Multi-viscosity diesel engine oils are preferred.

Diesel fuel quality and fuel sulfur content must comply with all existing emissions regulations for the area in which the engine operates.

DO NOT use diesel fuel with sulfur content greater than 10000 mg/kg (10000 ppm).

DX,ENOIL11 -19-02NOV16-1/1

Engine Oil and Filter Service Intervals — Tier 3 and Stage IIIA — OEM Applications

Recommended oil and filter service intervals are based on a combination of oil pan capacity, type of engine oil and filter used, and sulfur content of the diesel fuel. Actual service intervals also depend on operation and maintenance practices.

Use oil analysis to evaluate the condition of the oil and to aid in selection of the proper oil and filter service interval. Contact your John Deere dealer for more information on engine oil analysis.

Change the oil and oil filter at least once every 12 months even if the hours of operation are fewer than the otherwise recommended service interval.

Diesel fuel sulfur content affects engine oil and filter service intervals.

- Use of diesel fuel with sulfur content less than 1000 mg/kg (1000 ppm) is RECOMMENDED.
- Use of diesel fuel with sulfur content 1000—2000 mg/kg (1000—2000 ppm) REDUCES the oil and filter service interval.
- BEFORE using diesel fuel with sulfur content greater than 2000 mg/kg (2000 ppm), contact your John Deere dealer.
- DO NOT use diesel fuel with sulfur content greater than 10000 mg/kg (10000 ppm).

- **Reduce oil and filter service intervals by 50% when using biodiesel blends greater than B20. Oil analysis may allow longer service intervals.**
- **Use only approved oil types.**

Approved Oil Types:

- "Plus-50 Oils" include John Deere Plus-50™ II and John Deere Plus-50™
- "Other Oils" include John Deere Torq-Gard™, API CK-4, API CJ-4, API CI-4 PLUS, API CI-4, ACEA E9, ACEA E7, ACEA E6, ACEA E5, and ACEA E4

NOTE: The 500 hour extended oil and filter change interval is only allowed if all of the following conditions are met:

- *Engine equipped with an extended drain interval oil pan*
- *Use of diesel fuel with sulfur content less than 2000 mg/kg (2000 ppm) for PowerTech™ Plus engines or 5000 mg/kg (5000 ppm) for PowerTech™ engine*
- *Use of John Deere Plus-50™ II or John Deere Plus-50™ oil*
- *Use of an approved John Deere oil filter*

Mixing of Lubricants

In general, avoid mixing different brands or types of oil. Oil manufacturers blend additives in their oils to meet certain specifications and performance requirements.

Mixing different oils can interfere with the proper functioning of these additives and degrade lubricant performance.

Consult your John Deere dealer to obtain specific information and recommendations.

DX,LUBMIX -19-18MAR96-1/1

Alternative and Synthetic Lubricants

Conditions in certain geographical areas may require lubricant recommendations different from those printed in this manual.

Some John Deere brand coolants and lubricants may not be available in your location.

Consult your John Deere dealer to obtain information and recommendations.

Synthetic lubricants may be used if they meet the performance requirements as shown in this manual.

The temperature limits and service intervals shown in this manual apply to both conventional and synthetic lubricants.

Re-refined base stock products may be used if the finished lubricant meets the performance requirements.

DX,ALTER -19-11APR11-1/1

Lubricant Storage

Your equipment can operate at top efficiency only when clean lubricants are used.

Use clean containers to handle all lubricants.

Store lubricants and containers in an area protected from dust, moisture, and other contamination. Store containers on their side to avoid water and dirt accumulation.

Make certain that all containers are properly marked to identify their contents.

Properly dispose of all old containers and any residual lubricant they may contain.

DX,LUBST -19-11APR11-1/1

Oil Filters

Filtration of oils is critical to proper operation and lubrication.

Always change filters regularly as specified in this manual.

Use filters meeting John Deere performance specifications.

DX,FILT -19-18MAR96-1/1

Diesel Engine Coolant (engine with wet sleeve cylinder liners)

Preferred Coolants

The following pre-mix engine coolants are preferred:

- **John Deere COOL-GARD™II**
- **John Deere COOL-GARD II PG**

COOL-GARD II pre-mix coolant is available in several concentrations with different freeze protection limits as shown in the following table.

COOL-GARD II pre-mix	Freeze Protection Limit
COOL-GARD II 20/80	-9 °C (16 °F)
COOL-GARD II 30/70	-16 °C (3 °F)
COOL-GARD II 50/50	-37 °C (-34 °F)
COOL-GARD II 55/45	-45 °C (-49 °F)
COOL-GARD II PG 60/40	-49 °C (-56 °F)
COOL-GARD II 60/40	-52 °C (-62 °F)

Not all COOL-GARD II pre-mix products are available in all countries.

Use COOL-GARD II PG when a non-toxic coolant formulation is required.

Additional Recommended Coolants

The following engine coolant is also recommended:

- John Deere COOL-GARD II Concentrate in a 40—60% mixture of concentrate with quality water.

IMPORTANT: When mixing coolant concentrate with water, do not use less than 40% or greater than 60% concentration of coolant. Less than 40% gives inadequate additives for corrosion protection. Greater than 60% can result in coolant gelation and cooling system problems.

Other Coolants

Other ethylene glycol or propylene glycol base coolants may be used if they meet the following specification:

- Pre-mix coolant meeting ASTM D6210 requirements
- Coolant concentrate meeting ASTM D6210 requirements in a 40—60% mixture of concentrate with quality water

If coolant meeting one of these specifications is unavailable, use a coolant concentrate or pre-mix coolant that has a minimum of the following chemical and physical properties:

- Provides cylinder liner cavitation protection according to either the John Deere Cavitation Test Method or a fleet study run at or above 60% load capacity
- Is formulated with a nitrite-free additive package
- Protects the cooling system metals (cast iron, aluminum alloys, and copper alloys such as brass) from corrosion

Water Quality

Water quality is important to the performance of the cooling system. Distilled, deionized, or demineralized water is recommended for mixing with ethylene glycol and propylene glycol base engine coolant concentrate.

Coolant Drain Intervals

Drain and flush the cooling system and refill with fresh coolant at the indicated interval, which varies with the coolant used.

When COOL-GARD II or COOL-GARD II PG is used, the drain interval is 6 years or 6000 hours of operation.

If a coolant other than COOL-GARD II or COOL-GARD II PG is used, reduce the drain interval to 2 years or 2000 hours of operation.

IMPORTANT: Do not use cooling system sealing additives or antifreeze that contains sealing additives.

Do not mix ethylene glycol and propylene glycol base coolants.

Do not use coolants that contain nitrites.

COOL-GARD is a trademark of Deere & Company

DX,COOL3 -19-15MAY13-1/1

Water Quality for Mixing with Coolant Concentrate

Engine coolants are a combination of three chemical components: ethylene glycol (EG) or propylene glycol (PG) antifreeze, inhibiting coolant additives, and quality water.

Water quality is important to the performance of the cooling system. Distilled, deionized, or demineralized water is recommended for mixing with ethylene glycol and propylene glycol base engine coolant concentrate.

All water used in the cooling system should meet the following minimum specifications for quality:

Chlorides	<40 mg/L
Sulfates	<100 mg/L
Total solids	<340 mg/L
Total dissolved I hardness	<170 mg/L
pH	5.5—9.0

IMPORTANT: Do not use bottled drinking water because it often contains higher concentrations of total dissolved solids.

Freeze Protection

The relative concentrations of glycol and water in the engine coolant determine its freeze protection limit.

Ethylene Glycol	Freeze Protection Limit
40%	-24 °C (-12 °F)
50%	-37 °C (-34 °F)
60%	-52 °C (-62 °F)
Propylene Glycol	**Freeze Protection Limit**
40%	-21 °C (-6 °F)
50%	-33 °C (-27 °F)
60%	-49 °C (-56 °F)

DO NOT use a coolant-water mixture greater than 60% ethylene glycol or 60% propylene glycol.

DX,COOL19 -19-15MAY13-1/1

Operating in Warm Temperature Climates

John Deere engines are designed to operate using recommended engine coolants.

Always use a recommended engine coolant, even when operating in geographical areas where freeze protection is not required.

IMPORTANT: Water may be used as coolant *in emergency situations only.*

Foaming, hot surface aluminum and iron corrosion, scaling, and cavitation occur when water is used as the coolant, even when coolant conditioners are added.

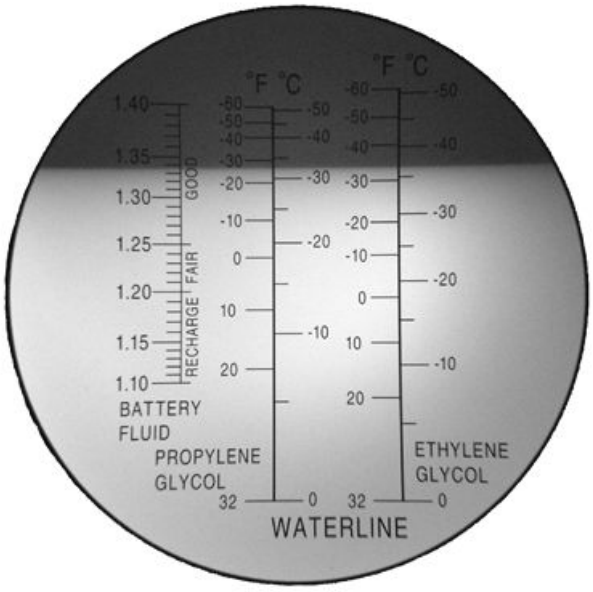
Drain cooling system and refill with recommended engine coolant as soon as possible.

DX,COOL6 -19-15MAY13-1/1

Testing Coolant Freeze Point

The use of a handheld coolant refractometer is the quickest, easiest, and most accurate method to determine coolant freeze point. This method is more accurate than a test strip or a float-type hydrometer which can produce poor results.

A coolant refractometer is available through your John Deere dealer under the SERVICEGARD™ tool program. Part number 75240 provides an economical solution to accurate freeze point determination in the field.



To use this tool:

1. Allow cooling system to cool to ambient temperatures.
2. Open radiator cap to expose coolant.
3. With the included dropper, collect a small coolant sample.
4. Open the lid of the refractometer, place one drop of coolant on the window and close the lid.
5. Look through the eyepiece and focus as necessary.
6. Record the listed freeze point for the type of coolant (ethylene glycol coolant or propylene glycol) being tested.

Disposing of Coolant

Improperly disposing of engine coolant can threaten the environment and ecology.

Use leakproof containers when draining fluids. Do not use food or beverage containers that may mislead someone into drinking from them.

Do not pour waste onto the ground, down a drain, or into any water source.

Inquire on the proper way to recycle or dispose of waste from your local environmental or recycling center, or from your John Deere engine distributor or servicing dealer.

John Deere PowerTech Plus™ OEM Engines have an electronic control system, which has the following controls and gauges as shown. The following information applies only to those controls and gauges supplied by John Deere. Refer to your engine application manual for specific guidelines if John Deere-sourced controls and instrumentation are not used.

Following is a brief description of the available optional electronic controls and gauges found on John Deere provided instrument panels. Refer to manufacturer's literature for information on controls not provided by Deere.

Instrument Panel (Continued)

A—Diagnostic Gauge/Hour Meter

The diagnostic gauge (A) displays diagnostic trouble codes (DTCs) as they are accessed. Other information on the engine can be accessed using the touch keys (N, O and P). The hour meter feature shows the operating hours of the engine and should be used as a guide for scheduling periodic maintenance. If the diagnostic gauge receives a trouble code from an engine control unit, the current display will switch to a warning or shutdown (depending on the severity of the code) screen that will display the trouble code number, the description of the code and the corrective action needed.

B—Tachometer

The tachometer (B) indicates engine speed in hundreds of revolutions per minute (rpm).

C—Voltmeter (Optional)

Continued on next page

The voltmeter (C) indicates system battery voltage. The amber “Warning” light (Q) will illuminate when battery voltage is too low for proper operation of the fuel injection system.

D—Audible Alarm (Optional)

The audible alarm (D) will sound whenever any of these abnormal conditions exist: low oil pressure, high coolant temperature, water-in-fuel, high fuel temperature, or high manifold temperatures. This includes all signals that light up the amber “warning” indicator (intermittent alarm) or the red “stop engine” indicator (steady alarm).

E—Audible Alarm Override Button

The optional audible alarm has an override button (E) that silences the audible alarm for approximately two minutes when pressed.

F—Key Start Switch

The three-position key start switch (F) controls the engine electrical system. When the key switch is turned clockwise to “START”, the engine will crank. When the engine starts, the key is released and returns to the “ON” (RUN) position.

G—Override Shutdown Rocker Switch

Switch will be present, but may not be active, depending on engine controller (ECU) options originally selected. If switch is active, pressing the upper half of the override shutdown switch (G) will override an engine shutdown signal. The switch must be pressed within 30 seconds to prevent undesired shutdown of engine. Pressing this switch will override the engine shutdown for 30 seconds at a time to move vehicle to a safe location.

H—Bump Speed Enable Rocker Switch

This is a three-position switch (H) with the center position as “OFF” (locked). With this switch in the “OFF” position, the speed select switch (I) is also locked, to prevent accidental changes in operating speed. Pressing upper or lower half of switch (H) will unlock or enable the bump speed switch to take effect using speed select switch (I).

I—Speed Select Rocker Switch

The speed select switch (I) is used to bump engine speed up (+) or down (-) in small increments during operation. This switch must be used with the bump speed enable switch (H) in the unlocked position (top or bottom half of button depressed).

J—High-Low Speed Select Rocker Switch

The high-low speed select switch (J) is used to set the engine operating speeds at slow (turtle) or fast (rabbit). Factory preset idle speeds can also be adjusted using bump speed enable switch (H) with speed select switch (I).

The basic instrument panel will have the high-low speed select switch only. Press and hold up (+) or down (-) to adjust engine speed as desired. The engine speed selected will not be held in the memory. To adjust engine speeds, See Changing Engine Speed in Section 20.

How To Select Preset Operating Speeds (Bump Speeds)

First select Turtle (Slow) or Adj by pressing speed select switch (J) to “Turtle” (slow) or “Adj”(center). Then you can press either the upper or lower portion of the bump speed enable switch (H) to unlock the setting. The bump speed enable must be held down as the speed select switch (J) is used to change the setting by pressing (+) to increase speed or (-) to decrease speed.

Once the slow idle speed has been set, the bump speed enable **switch must be pressed and released three times within two seconds to commit the new operating speed to memory.** If not done, the engine's new speed will only be effective until the key switch is shut off. Then the speed will revert back to the previous setting.

The fast idle speed is not adjustable. It will always go back to the factory preset fast idle speed.

K—Analog Throttle Control (Optional)

The throttle control (K) is used to control engine speed. This control is available only on engines with analog throttle.

L—Engine Oil Pressure Gauge

The oil pressure gauge (L) indicates engine oil pressure. An audible alarm (D) warns the operator if engine oil pressure falls below a safe operating pressure.

M—Engine Coolant Temperature Gauge

The engine coolant temperature gauge (M) indicates engine coolant temperature. An audible alarm (D) warns the operator if coolant temperature rises above the preset safe operating temperature.

N—Menu Key

The menu key is pressed to either enter or exit the menu screens on the diagnostic gauge.

O—Arrow Keys

Use the arrow keys (O) to change the display on the window of the diagnostic gauge and to access engine performance data.

Pressing the left arrow to scroll to the left or upward or the right arrow to scroll to the right or downward. This will allow you to view various engine parameters and any diagnostic trouble codes that occur.

Refer to the following story for accessing engine information on the diagnostic gauge using the touch keys.

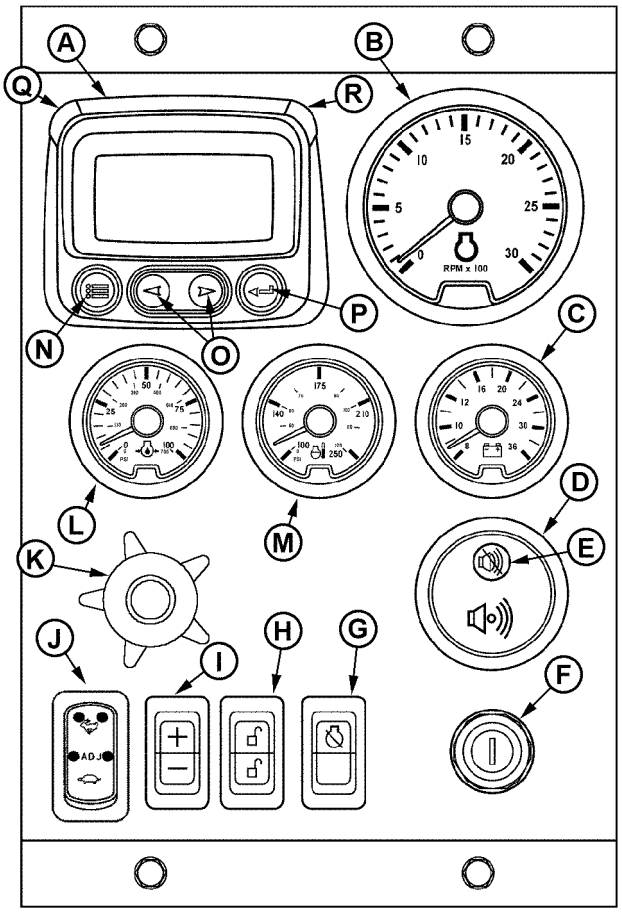
P—Enter Key

The enter key is pressed to select the parameter that is highlighted on the screen.

Q—Amber “WARNING” Indicator Light

Continued on next page

When light comes on, an abnormal condition exists. It is not necessary to shutdown engine immediately, but problem should be corrected as soon as possible. Screen on diagnostic gauge will display the problem and the solution needed.



PowerTech Plus is a trademark of Deere & Company

R—Red “STOP ENGINE” Indicator Light

When light comes on, stop engine immediately or as soon as safely possible to prevent engine damage. Correct problem before restarting.

Refer to your engine application manual for specific guidelines if John Deere-sourced controls and instrumentation are not used.

NOTE: This manual only covers operation of engine with a John Deere control system.

Following is a brief description of the available optional electronic controls and gauges found on John Deere provided instrument panels. Refer to manufacturer's literature for information on controls not provided by Deere.

Instrument Panels (Continued)

A—Diagnostic Gauge/Hour Meter

The diagnostic gauge (A) displays diagnostic trouble codes (DTCs) as they are accessed. Other information on the engine can be accessed using the touch keys (N, O and P). The hour meter feature shows the operating hours of the engine and should be used as a guide for scheduling periodic maintenance. If the diagnostic gauge receives a trouble code from an engine control unit, the current display will switch to a warning or shutdown (depending on the severity of the code) screen that will display the trouble code number, the description of the code and the corrective action needed.

B—Tachometer

The tachometer (B) indicates engine speed in hundreds of revolutions per minute (rpm).

C—Voltmeter (Optional)

Continued on next page

The voltmeter (C) indicates system battery voltage. The amber “Warning” light (Q) will illuminate when battery voltage is too low for proper operation of the fuel injection system.

D—Audible Alarm (Optional)

The audible alarm (D) will sound whenever low oil pressure, high coolant temperature, or water-in-fuel conditions exist. This includes all signals that light up the amber “warning” indicator (intermittent alarm) or the red “stop engine” indicator (steady alarm).

E—Audible Alarm Override Button

The optional audible alarm has an override button (E) that silences the audible alarm for approximately two minutes when pressed.

F—Key Start Switch

The three-position key start switch (F) controls the engine electrical system. When the key switch is turned clockwise to “START”, the engine will crank. When the engine starts, the key is released and returns to the “ON” (RUN) position.

G—Override Shutdown Rocker Switch

Switch will be present, but may not be active, depending on engine control unit (ECU) options originally selected. If switch is active, pressing the upper half of the override shutdown switch (G) will override an engine shutdown signal. The switch must be pressed within 30 seconds to prevent undesired shutdown of engine. Pressing this switch will override the engine shutdown for 30 seconds at a time to move vehicle to a safe location.

H—Bump Speed Enable Rocker Switch

This is a three-position switch (H) with the center position as “OFF” (locked). With this switch in the “OFF” position, the speed select switch (I) is also locked, to prevent accidental changes in operating speed. Pressing upper or lower half of switch (H) will unlock or enable the bump speed switch to take effect using speed select switch (I).

I—Speed Select Rocker Switch

The speed select switch (I) is used to bump engine speed up (+) or down (-) in small increments during operation. This switch must be used with the bump speed enable switch (H) in the unlocked position (top or bottom half of button depressed).

J—High-Low Speed Select Rocker Switch

The high-low speed select switch (J) is used to set the engine operating speeds at slow (turtle) or fast (rabbit). Factory preset idle speeds can also be adjusted using bump speed enable switch (H) with speed select switch (I).

The basic instrument panel will have the high-low speed select switch only. Press and hold up (+) or down (-) to adjust engine speed as desired. The engine speed selected will not be held in the memory. To adjust engine speeds, See Changing Engine Speeds in Section 20.

How To Select Preset Operating Speeds (Bump Speeds)

First select Turtle (Slow) or Adj by pressing speed select switch (J) to “Turtle” (slow) or “Adj”(center). Then you can press either the upper or lower portion of the bump speed enable switch (H) to unlock the setting. The bump speed enable must be held down as the speed select switch (J) is used to change the setting by pressing (+) to increase speed or (-) to decrease speed.

Once the slow idle speed has been set, the bump speed enable **switch must be pressed and released three times within two seconds to commit the new operating speed to memory.** If not done, the engine's new speed will only be effective until the key switch is shut off. Then the speed will revert back to the previous setting.

The fast idle speed is not adjustable. It will always go back to the factory preset fast idle speed.

K—Analog Throttle Control (Optional)

The throttle control (K) is used to control engine speed. This control is available only on engines with analog throttle.

L—Engine Oil Pressure Gauge

The oil pressure gauge (L) indicates engine oil pressure. An audible alarm (D) warns the operator if engine oil pressure falls below a safe operating pressure.

M—Engine Coolant Temperature Gauge

The engine coolant temperature gauge (M) indicates engine coolant temperature. An audible alarm (D) warns the operator if coolant temperature rises above the preset safe operating temperature.

N—Menu Key

The menu key is pressed to either enter or exit the menu screens on the diagnostic gauge.

O—Arrow Keys

Use the arrow keys (O) to change the display on the window of the diagnostic gauge and to access engine performance data.

Pressing the left arrow to scroll to the left or upward or the right arrow to scroll to the right or downward. This will allow you to view various engine parameters and any diagnostic trouble codes that occur.

Refer to the following story for accessing engine information on the diagnostic gauge using the touch keys.

P—Enter Key

The enter key is pressed to select the parameter that is highlighted on the screen.

Q—Amber “WARNING” Indicator Light

Continued on next page

When light comes on, an abnormal condition exists. It is not necessary to shut down the engine immediately, but the problem should be corrected as soon as possible.

When light comes on, stop engine immediately or as soon as safely possible to prevent engine damage. Correct problem before restarting.

R—Red “STOP ENGINE” Indicator Light

Accessing Active Trouble Codes

NOTE: The engine does not need to be running to navigate the diagnostic gauge screens. If engine start up is desired, See Starting The Engine. All of the engine values illustrated on the diagnostic gauge indicate the engine is running.

For description of trouble codes, see chart in Troubleshooting Section.

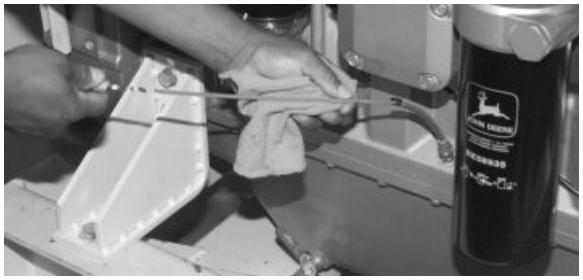
John Deere PowerSight

John Deere PowerSight is a web based service that allows remote access to machine data. John Deere PowerSight is accessible from a laptop, desktop or mobile device.

John Deere PowerSight works by combining a controller that includes cellular communication and GPS antennas. Machine data is collected by the controller and wirelessly transferred to a data server, where it is made available on a website.



John Deere PowerSight allows you to:

- Stay informed on machine location and hours
- Protect assets with Geofence and Curfew alerts
- Keep assets running with maintenance tracking and preventive maintenance plans
- Track and analyze machine and fuel usage
- Conduct remote machine diagnostics and programming

For more information and availability, contact an authorized John Deere dealer or servicing dealer.

Engine Break-In Service

Check Engine Oil

RG9924 —UN—17NOV99

RG8707A —UN—03SEP99

Crosshatch Pattern on Dipstick

A—Crosshatch Pattern

The engine is ready for normal operation. However, extra care during the first 100 hours of operation will result in more satisfactory long-term engine performance and life. DO NOT exceed 100 hours of operation with break-in oil.

1. This engine is factory-filled with John Deere DIESEL ENGINE BREAK-IN OIL (SAE 10W-30). Operate the engine at heavy loads with minimal idling during the break-in period.
2. If the engine has significant operating time at idle, constant speeds, and/or light load usage, or makeup oil is required in the first 100 hour period, a longer break-in period may be required. In these situations, an additional 100 hour break-in period is recommended using a new change of John Deere DIESEL ENGINE BREAK-IN OIL and a new John Deere oil filter.

IMPORTANT: DO NOT add makeup oil until the oil level is BELOW the ADD mark on dipstick. John Deere ENGINE BREAK-IN OIL (TY22041) should be used to make up any oil consumed during the break-in period.

3. Check engine oil level more frequently during engine break-in period. If oil must be added during this period, John Deere DIESEL ENGINE BREAK-IN OIL is preferred. See DIESEL ENGINE BREAK-IN OIL, in Fuels, Lubricants, and Coolant Section for other oils allowed.

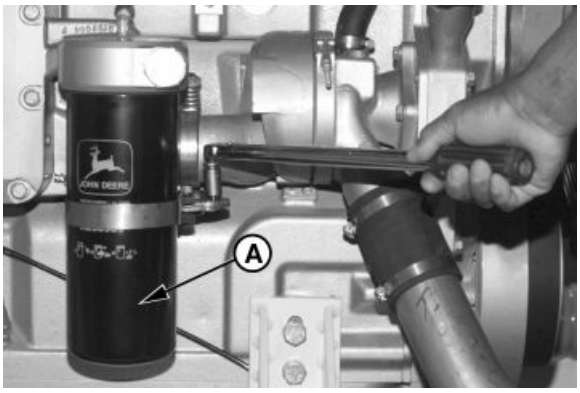
IMPORTANT: Do not use PLUS-50 oil or engine oils meeting any of the following during the first 100 hours of operation of a new or rebuilt engine:

API CJ-4	**API CF**
API CI-4 PLUS	**ACEA E7**
API CI-4	**ACEA E6**
API CH-4	**ACEA E5**
API CG-4	**ACEA E4**
API CF-4	**ACEA E3**
API CF-2	

These oils will not allow the engine to break-in properly.

DO NOT fill above the crosshatch pattern (A) or the FULL mark, whichever is present. Oil levels anywhere within the crosshatch are considered in the acceptable operating range.

Continued on next page



OURGP11,0000070 -19-01DEC14-1/3

4. During the first 20 hours, avoid prolonged periods of engine idling or sustained maximum load operation. If engine will idle longer than 5 minutes, stop engine.
5. Before the first 100 hours (maximum), change engine oil and replace engine oil filter (A). (See CHANGING ENGINE OIL AND REPLACING FILTER in Lubrication and Maintenance/500 Hour/12 Month Section.) Fill crankcase with the normal seasonal viscosity grade oil. (See DIESEL ENGINE OIL, in Fuels, Lubricants, and Coolant Section.)

NOTE: Some increase in oil consumption may be expected when low viscosity oils are used. Check oil levels more frequently.

If temperature is below 0°C (32°F), it may be necessary to use cold weather starting aids (See COLD WEATHER OPERATION, later in this section).

If air temperature is below -25°C (-13°F), use an engine block heater.

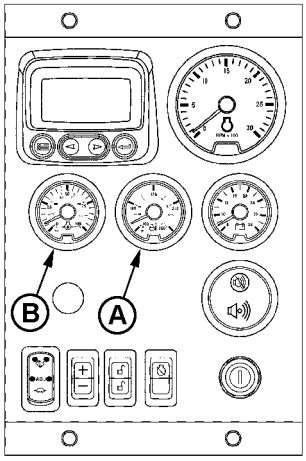
6. Watch coolant temperature gauge (A) closely. If coolant temperature rises above 100°C (212°F), reduce load on engine. Unless temperature drops quickly, stop the engine and determine the cause before resuming operation.



NOTE: When the coolant temperature gauge reads approximately 112°C (234°F), the engine will shutdown automatically, if equipped with safety controls.

7. Watch oil pressure gauge (B) for pressure within specification.

	Specification
Engine Oil[1]—Minimum Pressure at No Load (Idle)	138 kPa (1.38 bar) (20 psi)
Engine Oil—Maximum Pressure at Full Load (Rated Speed)	310 kPa (3.1 bar) (45 psi)
Engine Coolant—Temperature Range	82°—92°C (180°—197°F)

8. Check poly-vee belt for proper alignment and seating in pulley grooves.

Generator Set (Standby) And All Other OEM Engine Applications

To ensure that your engine will deliver efficient standby operation when needed, start engine and run at rated speed (with 50%—70% load) for 30 minutes every 2 weeks. DO NOT allow engine to run for an extended period of time with no load.

Starting the Engine

The following instructions apply to the optional controls and instruments available through the John Deere Parts Distribution Network. The controls and instruments for your engine may be different from those shown here; always follow manufacturer's instructions.

⚠ CAUTION: Before starting engine in a confined building, install proper outlet exhaust ventilation equipment. Always use safety approved fuel storage and piping.

NOTE: If temperature is below 0°C (32°F), it may be necessary to use cold weather starting aids. (See COLD WEATHER OPERATION in this group.)

1. Perform all prestarting checks outlined in Lubrication and Maintenance/Daily section later in this manual.

2. Open the fuel supply shut-off valve, if equipped.

   Panels with optional analog throttle(s) (A) : Set high-low speed select rocker switch to slow (turtle), then push in on analog throttle handle or turn full counterclockwise to set analog throttle(s) to slow speed.

IMPORTANT: Do not operate the starter for more than 30 seconds at a time. To do so may overheat the starter. If the engine does not start the first time, wait at least 2 minutes before trying again. If engine does not start after four attempts, see Troubleshooting section.

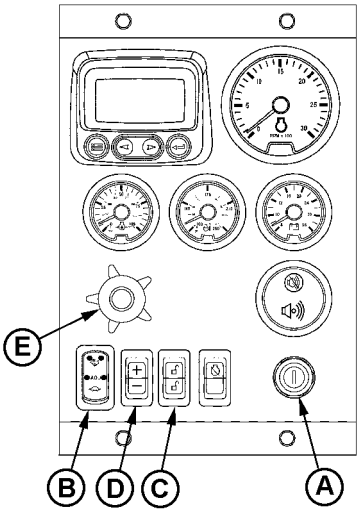
   Turn the key start switch (A) clockwise to crank the engine. When the engine starts, release the key switch so that it returns to the “ON” position.



IMPORTANT: If the key switch is released before the engine starts, wait until the starter and the engine stop turning before trying again. This will prevent possible damage to the starter and/or flywheel.

6. After engine starts, idle engine at not more than 1200 rpm until warm. (See WARMING ENGINE later in this section).

   Panels with high-low speed select rocker switch (B) only: Set rpm using bump speed enable switch (C) with speed select rocker switch (D).

   Panels with optional analog throttle (E): Set either high-low speed select switch (B) or analog throttle (E) to slow speed, and set desired speed with remaining control.

NOTE: Engine control unit (ECU) reads the higher of the high-low speed select rocker switch or the analog throttle speed settings.

OURGP11,000004E -19-12SEP06-1/1

Warming Engine

IMPORTANT: To ensure proper lubrication, operate engine at or below 1200 rpm with no load for 1—2 minutes. Extend this period 2—4 minutes when operating at temperatures below freezing.

Engines used in generator set applications where the ECU is programmed to lock engine at a specified speed, may not have a slow idle function. Operate these engines at high idle for 1 to 2 minutes before applying the load. This procedure does not apply to standby generator sets where the engine is loaded immediately upon reaching rated speed.

1. Check oil pressure gauge (A) as soon as engine starts. If gauge needle does not rise to minimum oil pressure of 138 kPa (1.38 bar) (20 psi) within 5 seconds, stop the engine and determine the cause. Normal engine oil pressure is 310 ± 103 kPa (3.10 ± 1.03 bar) (45 ± 15 psi) at rated full-load speed (1500—2100 rpm) with oil at normal operating temperature of 115°C (240°F).
2. Watch coolant temperature gauge (B). Do not place engine under full load until it is properly warmed up. The normal engine coolant temperature range is 82°—92°C (180°—197°F).

RG13724 —UN—11NOV04

Oil Pressure and Coolant Temperature Gauges On Panel

A—Engine Oil Pressure Gauge **B—Engine Coolant Temperature Gauge**

NOTE: It is a good practice to operate the engine under a lighter load and at lower speeds than normal for the first few minutes after start-up.

OMRGP15,0000124 -19-12SEP06-1/1

Normal Engine Operation

Observe engine coolant temperature and engine oil pressure. Temperatures and pressures will vary between engines and with changing operating conditions, temperatures, and loads.

Normal engine coolant operating temperature range is 82°—92°C (180°—197°F). If coolant temperature rises above 100°C (212°F), reduce load on engine. Unless temperature drops quickly, stop engine and determine cause before resuming operation.

Normal engine oil pressure at slow idle should be at least 138 kPa (20 psi) and should rise to 310 kPa (45 psi) at rated speed.

Operate the engine under a lighter load and at slower than normal speed for first 15 minutes after start-up. DO NOT run engine at slow idle.

IMPORTANT: Should the engine die while operating under load, immediately remove load and restart the engine. Overheating of the turbocharger parts may occur when oil flow is stopped.

Stop engine immediately if there are any signs of part failure. Symptoms that may be early signs of engine problems are:

- Sudden drop in oil pressure
- Abnormal coolant temperatures
- Unusual noise or vibration
- Sudden loss of power
- Excessive black exhaust
- Excessive fuel consumption
- Excessive oil consumption
- Fluid leaks

NOTE: These engines meet emission standards with an exhaust gas recirculation system and a variable geometry turbocharger. A revving sound may be heard for an instant after starting, as the variable geometry turbocharger recycles. This is normal.

OURGP11,000004F -19-19SEP06-1/1

Cold Weather Operation

CAUTION: Ether injector starting fluid is highly flammable. DO NOT use starting fluid on engines equipped with air intake heaters.

DO NOT use starting fluid near fire, sparks, or flames. DO NOT incinerate or puncture a starting fluid container.

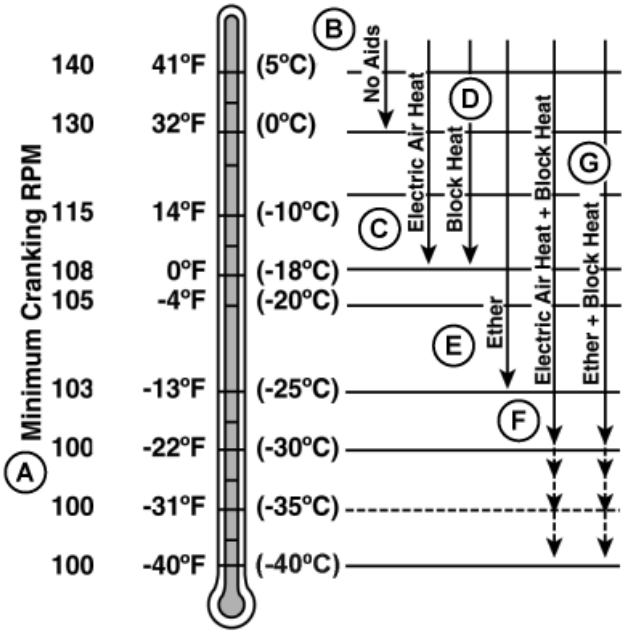
IMPORTANT: Engines with Rear PTO- Turn off or unload all pumps, auxiliary drives, and compressors before cold weather starting to reduce drag on engine.

Engines may be equipped with coolant heaters or ether injectors as cold weather starting aids.

Starting aids are required below 0°C (32°F). They will enhance starting performance above these temperatures and may be needed to start applications that have high parasitic loads during cranking and/or start acceleration to idle.

Using correct grade of oil (per engine and machine operator's manual) is critical to achieving adequate cold weather cranking speed. Synthetic oils have improved flow at low temperatures.

Other cold weather starting aids are required at temperatures below -25°C (-13°F) or at altitudes above 1500 m (5000 ft).



1. Follow steps 1—4 as listed under STARTING THE ENGINE, earlier in this section, then proceed as follows according to the instrument (gauge) panel on your engine.
2. Use cold weather starting aids as needed. Follow supplier instructions for starting aid provided on your engine. A booster battery can be connected if needed (see USING A BOOSTER BATTERY OR CHARGER, later in this section).
3. Follow remaining steps 5—7 as listed earlier in “Starting Engine” section.

   Additional information on cold weather operation is available from your authorized servicing dealer.

Changing Engine Speed

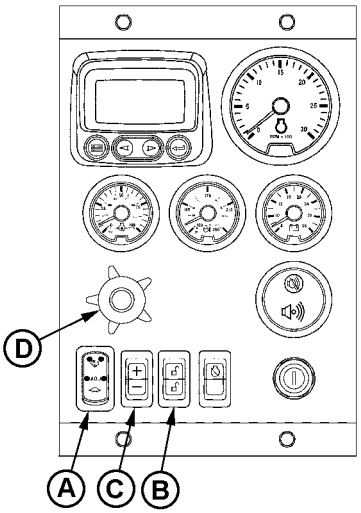
NOTE: On engines with **2-position** *throttles, speeds are not adjustable. These throttles allows operation only at the preset rated speed or at idle using the single switch (A).*

Changing from slow to fast speed using Standard High-Low Speed Select Rocker Switch (A) (If Equipped):

- For slow speed, press lower half of switch (indicated by turtle symbol).
- For fast speed, press upper half of switch (indicated by rabbit symbol).

NOTE: To adjust preset fast or slow speeds for High-Low Speed Select Rocker Switch:

1. *Select fast (rabbit) or slow (turtle) position on High-Low Speed Select Rocker Switch (A).*
2. *Press and hold top or bottom half of Bump Speed Enable Rocker Switch (B) while using Speed Select Rocker Switch (C).*
3. *Use Speed Select Rocker Switch (C) to bump engine speed up (+) or down (-).*



NOTE: Once the speed has been set, the Bump Speed Enable Switch (B) must be pressed and released three times within two seconds to commit the new slow or fast speed to memory. If not done, the engine's new slow or fast speed will only be effective until the key switch is shut off. Then the speed will revert to its previous setting.

Changing from slow to fast speed using Adjustable High-Low Speed Select Rocker Switch (A) (If Equipped):

Instrument panels have an adjustable **three-position** rocker switch (A) that can be used to select slow idle, fast idle, or an adjustable (“ADJ”) intermediate speed.

- For slow speed, press lower half of rocker switch (indicated by turtle symbol).
- For fast speed, press upper half of rocker switch (indicated by rabbit symbol).

NOTE: To adjust preset fast or slow speeds with adjustable High-Low Speed Select Rocker Switch:

3. *Use Speed Select Rocker Switch (C) to bump engine speed up (+) or down (-).*

NOTE: Slow (turtle) position is factory preset at low engine idle, while middle (ADJ) position is factory set at high engine idle.

NOTE: Once the speed has been set, the Bump Speed Enable Switch (B) must be pressed and released three times within two seconds to commit the new slow or fast speed to memory. If not done, the engine's new slow or fast speed will only be effective until the key is shut off. Then the speed will revert to its previous setting.

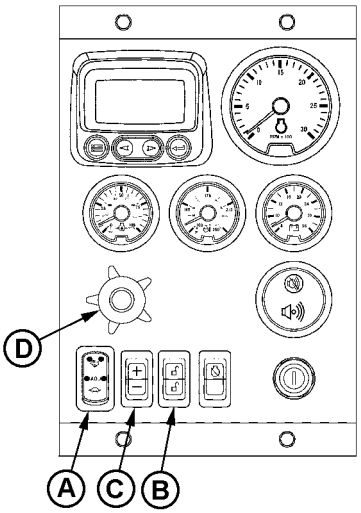
Changing engine speed using optional analog throttle control (D)



NOTE: Pushing in on analog throttle will immediately take engine to slow idle speed.

1. Set High-Low Speed Select Rocker Switch (A) to low speed position.

2. Turn analog throttle clockwise to increase speed or counterclockwise to decrease speed.

NOTE: Engine Control Unit (ECU) reads the higher of the High-Low Speed Select Rocker Switch or the Analog Throttle(s) Speed Settings. With High-Low switch at low speed, Analog Throttle(s) will control speed higher than low idle setting.

Avoid Excessive Engine Idling

Prolonged idling may cause the engine coolant temperature to fall below its normal range. This, in turn, causes crankcase oil dilution, due to incomplete fuel combustion, and permits formation of gummy deposits on valves, pistons, and piston rings. It also promotes rapid accumulation of engine sludge and unburned fuel in the exhaust system.

Once an engine is warmed to normal operating temperatures, engine should be idled at slow idle speed.

Slow idle speed for this engine is 850 rpm at factory. If an engine will be idling for more than 5 minutes, stop and restart later.

NOTE: Generator set applications where the ECU is locked at a specified speed may not have a slow idle function. These engines will idle at no-load governed speed (high idle).

RG,RG34710,7554 -19-12SEP06-1/1

Stopping the Engine

1. Pull PTO clutch lever rearward (away from engine) to disengage clutch, if equipped.

IMPORTANT: Before stopping an engine that has been operating at working load, idle engine at least 2 minutes at 1000—1200 rpm to cool hot engine parts.

Engines in generator set applications where the ECU is locked at a specified speed and no slow idle function is available, run engine for at least 2 minutes at fast idle and no load.

2. Run engine at 1000—1200 rpm for at least 2 minutes to cool.

   Panels with high-low speed select rocker switch (B) only: Set rpm using bump speed enable switch (C) with speed select rocker switch (D).

   Panels with optional analog throttle (E): Set either high-low speed select switch (B) or analog throttle control (E) to slow idle, and set desired speed with remaining control.

NOTE: Engine control unit (ECU) reads the higher of the high-low speed select rocker switch or the analog throttle speed settings.

3. Push in on analog throttle control handle (if equipped) so that engine goes to slow idle, or set slow speed with high-low speed select rocker switch.

4. Turn key start switch (A) to “OFF” position to stop the engine. Remove ignition key.

IMPORTANT: Make sure that exhaust stack rain cap (F) is installed when engine is not running. This will prevent water and dirt from entering engine.

Using a Booster Battery or Charger

A 12 volt booster battery can be connected in parallel (B) with battery(ies) on the unit to aid in cold weather starting. ALWAYS use heavy-duty jumper cables.

Series:

- Amps = Same as single battery
- Volts = Twice as a single battery

Parallel:

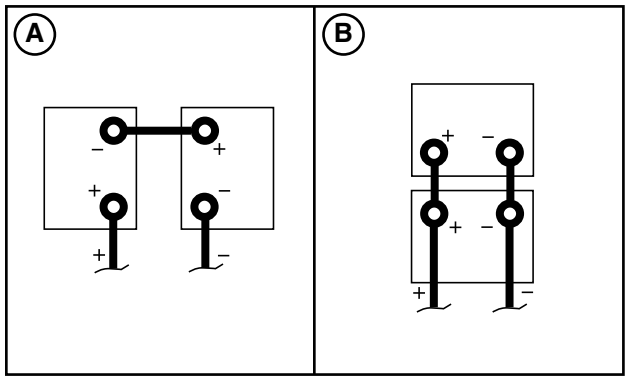
- Amps = Twice as a single battery
- Volts = Same as a single battery

CAUTION: Gas given off by battery is explosive. Keep sparks and flames away from battery. Before connecting or disconnecting a battery charger, turn charger off. Make last connection and first disconnection at a point away from battery. Always connect NEGATIVE (—) cable last and disconnect this cable first.

IMPORTANT: Be sure that polarity is correct before making connections. Reversed polarity will damage electrical system. Always connect positive to positive and negative to ground. Always use 12 volt booster battery for 12 volt electrical systems and 24 volt booster battery(ies) for 24 volt electrical systems.

WARNING: Battery posts, terminals, and related accessories contain lead and lead compounds, chemicals known to the State of California to cause cancer and reproductive harm. **Wash hands after handling.**

1. Connect booster battery or batteries to produce the required system voltage for your engine application.



NOTE: To avoid sparks, DO NOT allow the free ends of jumper cables to touch the engine.

2. Connect one end of jumper cable to the POSITIVE (+) post of the booster battery.
3. Connect the other end of the jumper cable to the POSITIVE (+) post of battery connected to starter.

4. Connect one end of the other jumper cable to the NEGATIVE (—) post of the booster battery.
5. ALWAYS complete the hookup by making the last connection of the NEGATIVE (—) cable to a good ground on the engine frame and away from the battery(ies).
6. Start the engine. Disconnect jumper cables immediately after engine starts. Disconnect NEGATIVE (—) cable first.

Observe Service Intervals

Using hour meter (A) on diagnostic gauge as a guide, perform all services at the hourly intervals indicated on following pages. At each scheduled maintenance interval, perform all previous maintenance operations in addition to the ones specified. Keep a record of hourly intervals and services performed, using charts provided in Lubrication and Maintenance Records section.

IMPORTANT: Recommended service intervals are for normal operating conditions. Perform maintenance at interval which occurs first, for example, either at 500 hours of operation OR every 12 months. Service MORE OFTEN if engine is operated under adverse conditions. Neglecting maintenance can result in failures or permanent damage to the engine.

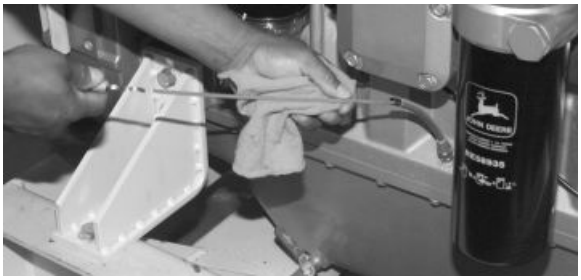
Daily Prestarting Checks

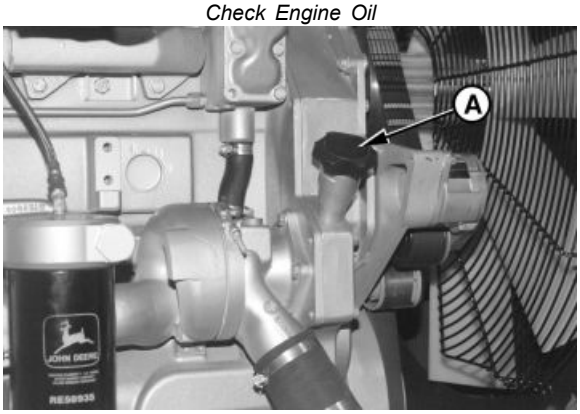
Do the following BEFORE STARTING THE ENGINE for the first time each day:



IMPORTANT: DO NOT add makeup oil until the oil level is BELOW the ADD mark.

1. Check engine oil level on dipstick. Add as required, using seasonal viscosity grade oil. (See DIESEL ENGINE OIL in Fuels, Lubricants, and Coolant section for oil specifications.)

   Oil may be added at timing gear cover filler cap (A) or oil pan filler adapter ports (B), if equipped.



IMPORTANT: DO NOT fill above the top of crosshatch area (C) on the dipstick. Oil levels anywhere within crosshatch are considered in the acceptable operating range.

2. Check the coolant level when engine is cold. Coolant level should be at bottom of filler neck. Fill radiator (A) with proper coolant solution if level is low. (See ADDING COOLANT in Service as Required section.) Check overall cooling system for leaks.

3. If the air cleaner has an automatic dust unloader valve (A), squeeze the unloader valve on air cleaner assembly to clear away any dust buildup.

WARNING: Battery posts, terminals, and related accessories contain lead and lead compounds, chemicals known to the State of California to cause cancer and reproductive harm. **Wash hands after handling.**

1. On regular batteries, check electrolyte level. Fill each cell to bottom of filler neck with distilled water.

NOTE: Low-maintenance or maintenance-free batteries should require little additional service. However, electrolyte level can be checked by cutting the center section of decal on dash-line, and removing cell plugs. If necessary, add clean, soft water to bring level to bottom of filler neck.

2. Keep batteries clean by wiping them with a damp cloth. Keep all connections clean and tight. Remove any corrosion, and wash terminals with a solution of 1 part baking soda and 4 parts water. Tighten all connections securely.

NOTE: Coat battery terminals and connectors with a mixture of petroleum jelly and baking soda to retard corrosion.

3. Keep battery fully charged, especially during cold weather. If a battery charger is used, turn charger off before connecting charger to battery(ies). Attach POSITIVE (+) battery charger lead to POSITIVE (+) battery post. Then attach NEGATIVE (—) battery charger lead to a good ground.

Changing Engine Oil and Replacing Oil Filter

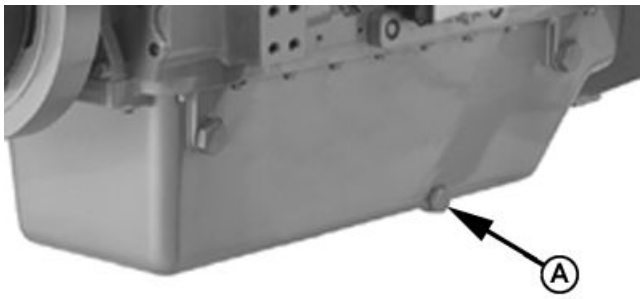
IMPORTANT: Changing engine oil and filter every 500 hours or 12 months depends on the following requirements:

- **Engine equipped with an extended drain interval oil pan.**
- **Use of diesel fuel with sulfur content less than 0.50% (5000 ppm) is strongly recommended.**
- **Use of premium oil John Deere PLUS-50, ACEA E7 or ACEA E6.**
- **Perform engine oil analysis to determine the actual extended service life of ACEA E7 and ACEA E6 oils.**
- **Use of the approved John Deere oil filter.**

The oil and filter change interval is reduced if ANY of the above listed requirements are not followed. (Refer to DIESEL ENGINE OIL AND FILTER SERVICE INTERVALS, in Fuels, Lubricants, and Coolant Section.)

NOTE: During **break-in***, change engine oil and filter for the first time before* **100** *hours maximum of operation.*

OILSCAN® and OILSCAN PLUS® are John Deere sampling programs to help you monitor machine performance and identify potential problems before they cause serious damage. OILSCAN™ and OILSCAN PLUS™ kits are available from your John Deere dealer. Oil samples should be taken prior to the oil change. Refer to instructions provided with kit.



CAUTION: Metal surfaces of engine may be hot to the touch after shutdown.

Change engine oil as follows:

NOTE: Drain plug location may vary, depending on the application.

1. Run engine approximately 5 minutes to warm up oil. Shut off engine.
2. Remove oil pan drain plug (A).
3. Drain crankcase oil from engine while warm.

NOTE: For more complete draining of oil, wait to install oil pan drain plug until filter oil is drained back (see following procedure).

4. Remove and discard oil filter element using a suitable filter wrench (A).
5. Remove oil filter packing and clean filter mounting pad.

IMPORTANT: Filtration of oils is critical to proper lubrication. Always change filter regularly. Use filter meeting John Deere performance specifications.

6. Oil new packing and install new filter element onto filter housing. Hand tighten element according to values printed on filter element. If values are not provided, tighten element approximately 1/2—3/4 turn after packing contacts filter housing. DO NOT overtighten filter element.

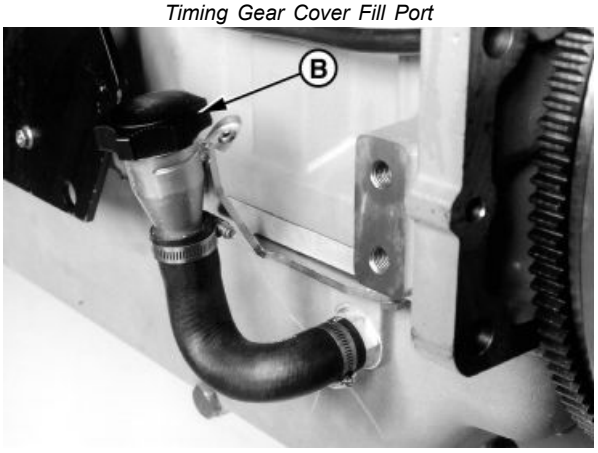
9. Fill engine crankcase with correct John Deere engine oil through timing gear cover fill port (A) or oil pan fill port (B) depending on engine application. (See DIESEL ENGINE OIL in Fuels, Lubricants, and Coolant section for determining correct engine oil.)

   To determine the correct oil fill quantity for your engine, see ENGINE CRANKCASE OIL FILL QUANTITIES in the Specifications section.

NOTE: Crankcase oil capacity may vary slightly. ALWAYS fill crankcase to full mark or within crosshatch on dipstick, whichever is present. DO NOT overfill.



IMPORTANT: Immediately after completing any oil change, crank engine for 30 seconds without permitting engine to start. This will help ensure adequate lubrication to engine components before engine starts.

10. Start engine and run to check for possible leaks.
11. Stop engine and check oil level after 10 minutes. Oil level reading should be within crosshatch of dipstick.

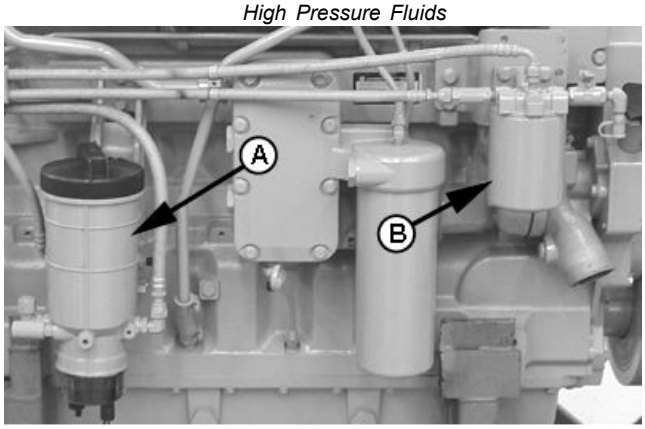
CAUTION: Escaping fluid under pressure can penetrate the skin causing serious injury. Relieve pressure before disconnecting fuel or other lines. Tighten all connections before applying pressure. Keep hands and body away from pinholes and nozzles which eject fluids under high pressure. Use a piece of cardboard or paper to search for leaks. Do not use your hand.



If any fluid is injected into the skin, it must be surgically removed within a few hours by a doctor familiar with this type injury or gangrene may result. IMPORTANT: The air intake system must not leak. Any leak, no matter how small, may result in internal engine damage due to abrasive dirt and dust entering the intake system.

1. Inspect all intake hoses (piping) for cracks. Replace as necessary.
2. Check clamps on piping which connect the air cleaner to the engine. Tighten clamps as necessary. This will help prevent dirt from entering the air intake system through loose connections, causing internal engine damage.

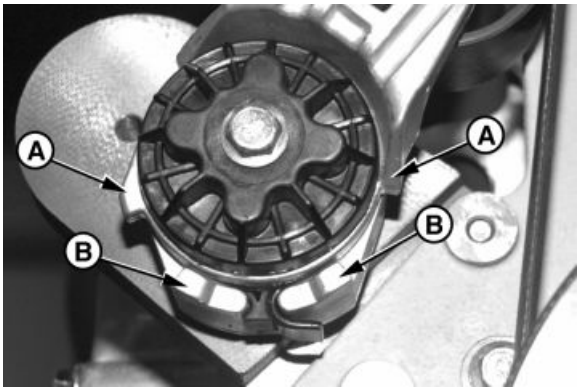
Checking Belt Tensioner Spring Tension and Belt Wear



Belt drive systems equipped with automatic (spring) belt tensioners cannot be adjusted or repaired. The automatic belt tensioners are designed to maintain proper belt tension over the life of the belt. If tensioner spring tension is not within specification, replace tensioner assembly.

Checking Belt Wear

The belt tensioner is designed to operate within the limit of arm movement provided by the cast stops (A and B) when correct belt length and geometry is used.

Visually inspect cast stops (A and B) on belt tensioner assembly.

If the tensioner stop on swing arm (A) is hitting the fixed stop (B), check mounting brackets (alternator, belt tensioner, idler pulley, etc.) and the belt length. Replace belt as needed (see REPLACING FAN/ALTERNATOR V-BELTS in Service as Required section).

Checking Cooling System

⚠ CAUTION: Explosive release of fluids from pressurized cooling system can cause serious burns.

Shut off engine. Only remove filler cap when cool enough to touch with bare hands. Slowly loosen cap to first stop to relieve pressure before removing completely.

IMPORTANT: Air must be expelled from cooling system when system is refilled. Loosen temperature sending unit fitting or plug in thermostat housing to allow air to escape when filling system. Retighten fitting or plug when all the air has been expelled. Cooling system must be free of air by time engine coolant temperature reaches 80°C (176°F) or damage to EGR cooler may result.

1. Visually check entire cooling system for leaks. Tighten all clamps securely.

OURGP11,0000057 -19-12SEP06-1/1

Testing Diesel Engine Coolant

Maintaining adequate concentrations of glycol and inhibiting additives in the coolant is critical to protect the engine and cooling system against freezing, corrosion, and cylinder liner erosion and pitting.

Test the coolant solution at intervals of 12 months or less and whenever excessive coolant is lost through leaks or overheating.

Coolant Test Strips

Coolant test strips are available from your John Deere dealer. These test strips provide a simple, effective method to check the freeze point and additive levels of your engine coolant.

When Using John Deere COOL-GARD II

John Deere COOL-GARD II Premix™ , COOL-GARD II PG Premix and COOL-GARD II Concentrate are maintenance free coolants for up to six years or 6000 hours of operation, provided that the cooling system is topped off using only John Deere COOL-GARD II Premix or COOL-GARD II PG premix. Test the coolant condition annually with coolant test strips designed for use with John Deere COOL-GARD II coolants. If the test strip chart indicates that additive is required, add John Deere COOL-GARD II Coolant Extender as directed.

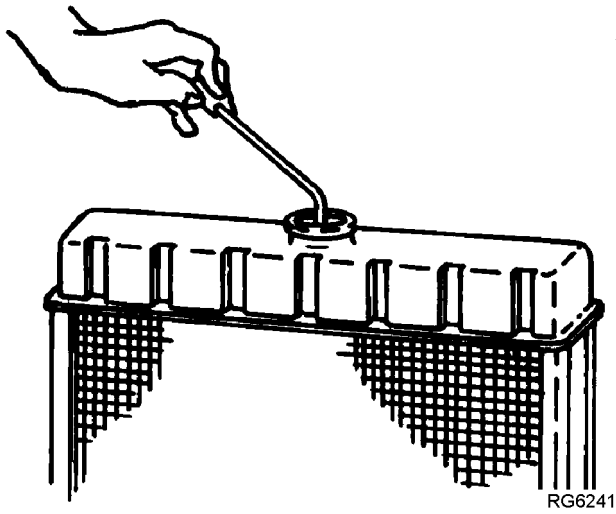
COOL-GARD is a trademark of Deere & Company

Add only the recommended concentration of John Deere COOL-GARD II Coolant Extender. DO NOT add more than the recommended amount.

When Using Nitrite-Containing Coolants

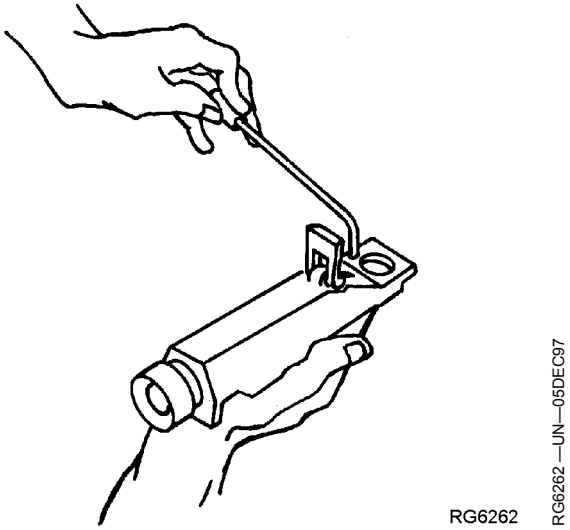
Compare the test strip results to the supplemental coolant additive (SCA) chart to determine the amount of inhibiting additives in your coolant and whether more John Deere Liquid Coolant Conditioner should be added.

Add only the recommended concentration of John Deere Liquid Coolant Conditioner. DO NOT add more than the recommended amount.



Coolant Analysis

For a more thorough evaluation of your coolant, perform a coolant analysis. The coolant analysis can provide critical data such as freezing point, antifreeze level, pH, alkalinity, nitrite content (cavitation control additive), molybdate content (rust inhibitor additive), silicate content, corrosion metals, and visual assessment.



Contact your John Deere dealer for more information on coolant analysis.

DX,COOL9 -19-11APR11-1/1

Replenishing Supplemental Coolant Additives (SCAs) Between Coolant Changes

Radiator Coolant Check

JT07298 Coolant/Battery Tester

IMPORTANT: Do not add supplemental coolant additives when the cooling system is drained and refilled with John Deere ANTIFREEZE/SUMMER COOLANT or John Deere COOL-GARD®.

NOTE: If a system is to be filled with coolant that does not contain SCAs, the coolant must be precharged. Determine the total system capacity and premix with 3% John Deere Coolant Conditioner.

Through time and use, the concentration of coolant additives is gradually depleted during engine operation. Periodic replenishment of inhibitors is required, even when John Deere ANTIFREEZE/SUMMER COOLANT is used. The cooling system must be recharged with additional supplemental coolant additives available in the form of liquid coolant conditioner.

Maintaining the correct coolant conditioner concentration (SCAs) and freeze point is essential in your cooling system to protect against rust, liner pitting and corrosion, and freeze-ups due to incorrect coolant dilution.

John Deere LIQUID COOLANT CONDITIONER is recommended as a supplemental coolant additive in John Deere engines.

DO NOT mix one brand of SCA with a different brand.

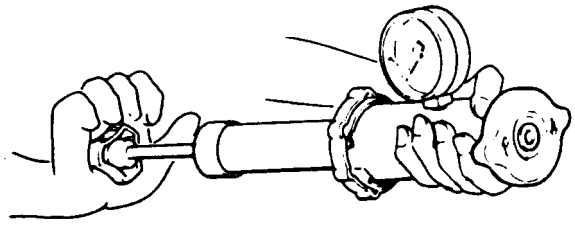
Test the coolant solution at 500 hours or 12 months of operation using either John Deere coolant test strips or a COOLSCAN ® analysis. If a COOLSCAN ® analysis is not available, recharge system per instructions printed on label of John Deere Liquid Coolant Conditioner.

IMPORTANT: ALWAYS maintain coolant at correct level and concentration. DO NOT operate engine without coolant for even a few minutes.

If frequent coolant makeup is required, the glycol concentration should be checked with JT07298 Coolant/Battery Tester to ensure that the desired freeze point is maintained. Follow manufacturer's instructions provided with refractometer.

Add the manufacturer's recommended concentration of supplemental coolant additive. DO NOT add more than the recommended amount.

The use of non-recommended supplemental coolant additives may result in additive drop-out and gelation of the coolant.



If other coolants are used, consult the coolant supplier and follow the manufacturer's recommendation for use of supplemental coolant additives.

See DIESEL ENGINE COOLANT and additional information on coolant additives in Fuels, Lubricants and Coolants earlier in this manual for proper mixing of coolant ingredients before adding to the cooling system.

Connect Gauge and Adapter to Filler Neck

A pressurized cooling system is required to protect engine from cavitation and oxidizing of coolant.

⚠ CAUTION: Explosive release of fluids from pressurized cooling system can cause serious burns.

Shut off engine. Only remove filler cap when cool enough to touch with bare hands. Slowly loosen cap to first stop to relieve pressure before removing completely.

Test Radiator Cap

1. Remove radiator cap and attach to D05104ST Tester as shown.
2. Pressurize cap to following specifications.[1]

Specification	
Radiator Cap—Test Pressure	103 kPa (1.03 bar) (15 psi)

Gauge should hold pressure for 10 seconds within the normal range if cap is acceptable. If gauge does not hold pressure, replace radiator cap.

3. Remove the cap from gauge, turn it 180°, and retest cap. This will verify that the first measurement was accurate.

[1]Test pressures recommended are for Deere OEM cooling system for 13.5 L engines. On specific vehicle applications, test cooling system and pressure cap according to the recommended pressure for that vehicle.

Test Cooling System

NOTE: Engine should be warmed up to test overall cooling system.

1. Allow engine to cool; carefully remove radiator cap.
2. Fill radiator with coolant to normal operating level.

IMPORTANT: DO NOT apply excessive pressure to cooling system. Doing so may damage radiator and hoses.

3. Connect gauge and adapter to filler neck. Pressurize cooling system to the following specifications.[1]

Specification	
Cooling System—Test Pressure	103 kPa (1.03 bar) (15 psi)

4. With pressure applied, check all cooling system hose connections, radiator, and engine for leaks.

If leakage is detected, correct as necessary and pressure test system again. If no leakage is detected, but the gauge indicated a drop in pressure, contact your engine distributor or servicing dealer for further diagnostics.

IMPORTANT: Modification or alteration of the unit fuel injectors in ways not recommended by the manufacturer will terminate the warranty obligation to the purchaser.

In addition, tampering with fuel system which alters emission-related equipment on engines may result in fines or other penalties, per EPA regulations or other local emission laws.

Adding Coolant

CAUTION: Explosive release of fluids from pressurized cooling system can cause serious burns.

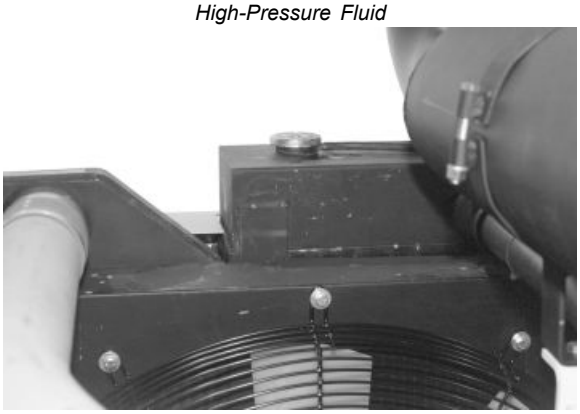
Shut off engine. Only remove filler cap when cool enough to touch with bare hands. Slowly loosen cap to first stop to relieve pressure before removing completely.

IMPORTANT: Never pour cold liquid into a hot engine, as it may crack cylinder head or block. DO NOT operate engine without coolant for even a few minutes.

John Deere Cooling System Sealer may be added to the radiator to stop leaks on a temporary or emergency basis only. DO NOT use any other stop-leak additives in the cooling system. Leaks should be permanently repaired as quickly as possible.

Air must be expelled from cooling system when coolant is added. Cooling system must be free of air by time engine coolant temperature reaches 80°C (176°F) or damage to EGR cooler may result.

1. Loosen temperature sending unit fitting or plug in thermostat housing to allow air to escape when filling system.



IMPORTANT: When adding coolant to the system, use the appropriate coolant solution. (See DIESEL ENGINE COOLANTS, SUPPLEMENTAL ADDITIVE INFORMATION in Fuels, Lubricants, and Coolant section for mixing of coolant ingredients before adding to cooling system.)

Do not overfill cooling system. A pressurized system needs space for heat expansion without overflowing at top of radiator.

Fill Cooling System

2. Fill until coolant level touches bottom of radiator filler neck or to “FULL HOT” mark on coolant recovery tank..
3. Check freeze temperature protection.
4. Tighten plugs and fittings after filling cooling system.
5. Run engine for 10 minutes to remove any air from system. Top off coolant level if required.

OURGP11,000005A -19-12OCT06-1/1

Pre-Start Cleaning Guide

IMPORTANT: Before cleaning machine, allow ample time for hot surfaces to cool.

IMPORTANT: Do not direct high-pressure spray from hose output directly at or close to electrical connections and sensors.

Rigorous cleaning as needed is recommended. Clean more frequently during heavy machine use, and when weather conditions are dry.

- Check enclosed areas daily. Clean the engine and other enclosed areas of equipment to remove debris and any buildup of oil and grease. Keep the engine and engine compartment free of combustible material.
- Check for debris buildup daily on and around intake systems, exhaust systems, and intercooler piping systems. Verify that there are no holes or leaks in intake or exhaust systems. Do not allow debris to build up near hot exhaust components. Verify that hot exhaust components are cleaned as often as environmental conditions require.
- Inspect cooling system daily to determine whether cooling system needs cleaning. Visible buildup of residue that blocks airflow may degrade machine performance and requires more frequent cleaning depending on environmental conditions.
- Inspect difficult to observe areas daily as conditions may require additional cleaning care to remove debris.
- Check for oil and fuel leaks daily. Replace or repair any sources of leaks, including gaskets, seals, breather tubes, fittings, and fluid lines.

Maintenance and Service Reminders

- Keep surfaces free of grease and oil.
- Clean up after hydraulic and other fluid leaks.
- Fuel Lines — Check for leaks, cracks, and kinks that require service before use.
- Fuel Pumps — Check fittings, especially compression ring couplings, for cracks and leaks.
- Fuel Injectors — Check pressure and return lines for signs of leaks.
- When servicing fuel filter or draining water separator, avoid fuel spills. Immediately clean up any fuel spill.
- Handle transmission and power steering fluids with care. Immediately clean up any spills, especially around fill points.
- Check for transmission case venting system seepage, transmission case leakage, power steering cylinder leakage, or power steering line leakage.
- Check for loose electrical connectors, damaged wiring, corrosion, and poor connections.

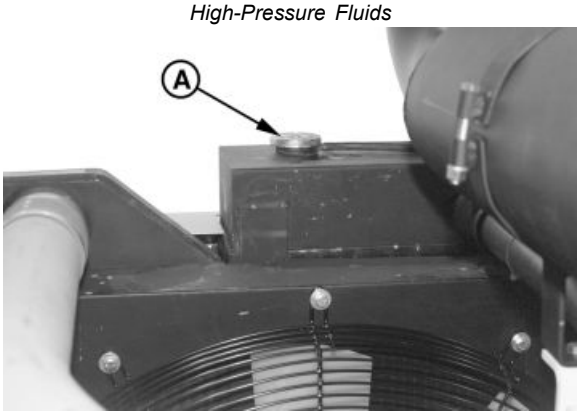
Flushing and Refilling Cooling System

CAUTION: Explosive release of fluids from pressurized cooling system can cause serious burns.

Shut off engine. Only remove filler cap when cool enough to touch with bare hands. Slowly loosen cap to first stop to relieve pressure before removing completely.

NOTE: Coolant drain intervals can vary greatly depending on coolant type used and maintenance preformed. Please see the section Fuels, Lubricants, and Coolants earlier in this manual for specific interval information.

Drain old coolant, flush the entire cooling system, test thermostats, and fill with recommended clean coolant.



1. Pressure test entire cooling system and pressure cap if not previously done. (See PRESSURE TESTING COOLING SYSTEM, in Lubrication and Maintenance/500 Hour/12 Month section.)
2. Slowly open the engine cooling system filler cap or radiator cap (A) to relieve pressure and allow coolant to drain faster.

6. Test thermostat opening temperature. (See TESTING THERMOSTATS OPENING TEMPERATURE later in this section.)
7. Close all drain valves after coolant has drained.

⚠ CAUTION: Do not run engine longer than 10 minutes. Doing so may cause engine to overheat which may cause burns when radiator water is draining.

8. Fill the cooling system with clean water. Run the engine about 10 minutes to stir up possible rust or sediment.
9. Stop engine, pull off lower radiator hose and remove radiator cap. Immediately drain the water from system before rust and sediment settle.
10. After draining water, close drain valves. Reinstall radiator cap and radiator hose and clamp. Fill the cooling system with clean water and a heavy duty cooling system cleaner such as FLEETGUARD® RESTORE™ and RESTORE PLUS™. Follow manufacturer's directions on label.
11. After cleaning the cooling system, drain cleaner and fill with water to flush the system. Run the engine about 10 minutes, remove radiator cap and pull off lower radiator hose, then drain out flushing water.

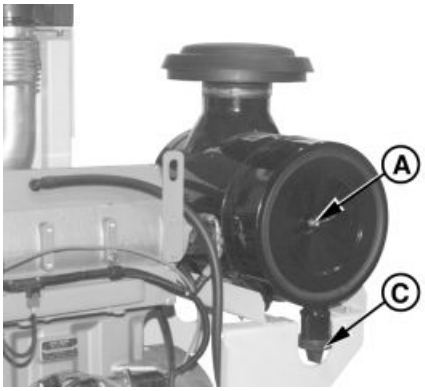
Replacing Air Cleaner Filter Elements

IMPORTANT: ALWAYS REPLACE primary air cleaner element when air restriction indicator shows a vacuum of 625 mm (25 in.) H_2O, is torn, or visibly dirty.

NOTE: This procedure applies to John Deere air cleaner kits. Refer to manufacturer's instructions for servicing air cleaners not supplied by John Deere.



1. Remove wing nut (A) and remove canister cover and primary filter assembly (B) from canister.

IMPORTANT: Remove secondary (safety) air cleaner element (E) ONLY for replacement. DO NOT attempt to clean, wash, or reuse secondary element. Replacement of secondary element is usually necessary ONLY when primary element has a hole in it or restriction indicator green dot (•) has disappeared from window.

2. Thoroughly clean all dirt from inside canister.
3. Squeeze dust unloader valve (C) on canister to remove all dust.
4. Observe secondary (safety) element restriction indicator/retaining nut (D). If green dot (•) has disappeared from window, replace secondary element.
5. To replace secondary element, remove restriction indicator/retaining nut and secondary element. Immediately replace secondary element with new element to prevent dust from entering air intake system. Tighten restriction indicator/retaining nut to specifications.

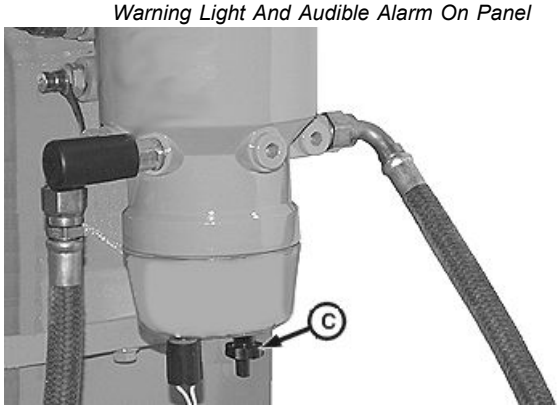
Draining Fuel Filter Water Separator Bowl

Your engine is equipped with a sensor that detects the presence of water in separator bowl mounted below fuel filter. This sensor will illuminate the red “STOP ENGINE” warning light (A) on instrument panel and also sound an audible alarm (B). A diagnostic trouble code (DTC) displayed on the diagnostic gauge will indicate that there is water in the fuel bowl (see LISTING OF DIAGNOSTIC TROUBLE CODES in Section 55).

ALWAYS STOP ENGINE IMMEDIATELY and drain water separator bowl when these warnings occur.



1. Drain water and contaminants from water separator sediment bowl by opening drain valve (C) and operating primer until fuel is clear of water.
2. Close drain valve.

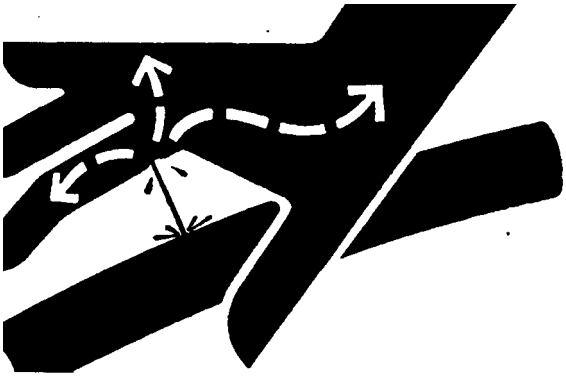
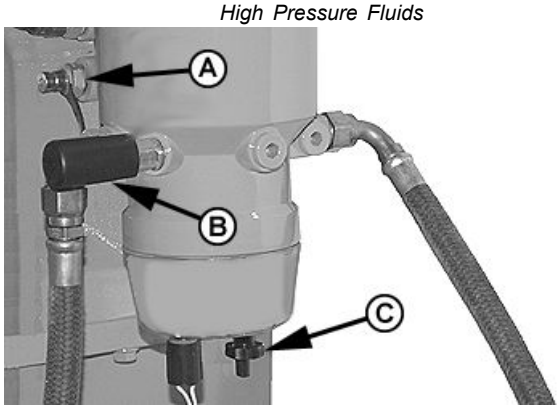
Bleeding Fuel System (Earlier Engines)



CAUTION: Escaping fluid under pressure can penetrate the skin causing serious injury. Relieve pressure before disconnecting fuel or other lines. Tighten all connections before applying pressure. Keep hands and body away from pinholes and nozzles which eject fluids under high pressure. Use a piece of cardboard or paper to search for leaks. Do not use your hand.

If any fluid is injected into the skin, it must be surgically removed within a few hours by a doctor familiar with this type injury or gangrene may result. Doctors unfamiliar with this type of injury may call the Deere & Company Medical Department in Moline, Illinois, or other knowledgeable medical source.

IMPORTANT: Fuel filter must be replaced whenever audible alarm sounds and trouble code indicates plugged filter (fuel supply pressure moderately/extremely low). Replace fuel filter at 12 month intervals (or every 500 hours) if no alarm/code indications occur.



NOTE: Under normal conditions, fuel system bleeding is not required. Priming system with hand primer (B) is normally sufficient. If necessary to bleed the system, use the following procedure.

1. Drain water and contaminants from water separator sediment bowl by opening drain valve (C) and operating primer (B) until fuel is clear of water.
2. Attach an open line to diagnostic port (A) and place end of line in suitable container for diesel fuel.
3. Pump hand primer (B) until a steady flow of fuel (without bubbles) comes out of line.

Bleeding Fuel System (Later Engines)

NOTE: Normally, the fuel system on these engines is self-priming and self-bleeding, and does not require a bleeding procedure by the operator.

If engine will not start after filter changes, turn ignition key ON for 60 seconds to prime the fuel system. It may be necessary to turn the key off and on again to reprime the system before starting.

Replacing Fan/Alternator V-Belts

Refer to CHECKING BELT TENSIONER SPRING TENSION AND BELT WEAR in Lubrication and Maintenance/500 Hour/12 Month section to determine if V-belts need replacing.

NOTE: While belt is removed, inspect pulleys and bearings. Rotate and feel for hard turning or any unusual sounds. If pulleys or bearings need replacement, see your John Deere dealer.

NOTE: This engine is equipped with automatic belt tensioners which do not require adjustment.

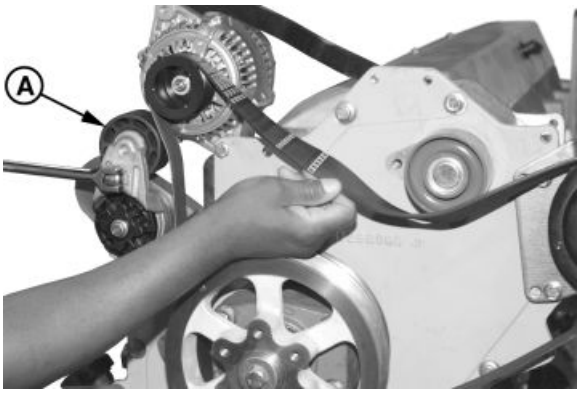
To Replace Lower V-Belt

IMPORTANT: ALWAYS replace belts as a matched set.



1. Release tension on lower belt using a 3/4-in. drive tool in square hole in end of lower tensioner arm (A).
2. Remove V-belt from pulleys and discard belt.
3. Install new belt; be sure that belt is correctly seated in all pulley grooves. (See V-BELT ROUTING, later in this section.)
4. Release belt tensioner to apply tension to belt. Remove drive tool.
5. Visually check belt alignment before starting engine.
6. Start engine and visually check belt alignment.

To Replace Upper V-Belt

IMPORTANT: ALWAYS replace belts as a matched set.

1. Remove lower V-belt as detailed earlier.
2. Release tension on upper V-belt using a 1/2-in. drive tool in upper tensioner arm (A).
3. Remove V-belt from pulleys and discard belt.
4. Install new belt; be sure that belt is correctly seated in all pulley grooves. (See V-BELT ROUTING, later in this section.)
5. Slowly release belt tensioner to apply tension to belt. Remove drive tool.

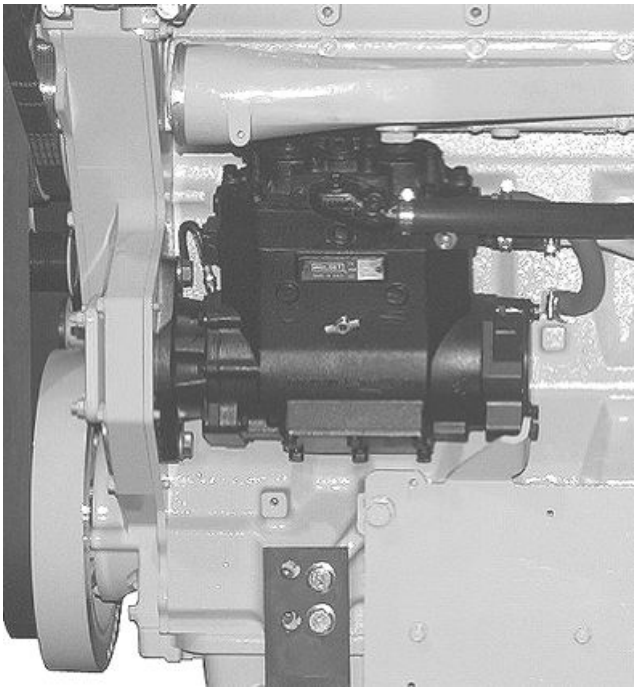
Checking Fuses

The main system fuse is located in the engine wiring harness. See ENGINE WIRING DIAGRAM in Troubleshooting section.

1. Open fuse holder in wiring harness.
2. Check fuse and replace as necessary with appropriate fuse.

Fuses are also provided in wiring for engine control unit (ECU) (20-amp) and fuel filters (15-amp). (See ENGINE WIRING DIAGRAM in Troubleshooting Section.)



OMRGP15,0000134 -19-08NOV10-1/1

Air Compressors

Air compressors are offered as options with John Deere OEM engines to provide compressed air to operate air-powered devices like vehicle air brakes.

Air compressors are engine-driven piston types. They are either air cooled or cooled with engine coolant. The compressors are lubricated with engine oil. The compressor runs continuously as gear or spline driven by the auxiliary drive of the engine but has “loaded” and “unloaded” operating modes. This is controlled by the vehicle's air system (refer to vehicle technical manual for complete air system checks and services).

See your John Deere engine distributor or servicing dealer for diagnostic and troubleshooting information. If diagnosis leads to an internal fault in the compressor, replace the complete compressor as a new or remanufactured unit.

Rear Power Take-Off (PTO)

CAUTION: Entanglement in rotating driveline can cause serious injury or death. Keep shield on PTO driveshaft between clutch housing and the engine driven equipment at all times during engine operation. Wear close fitting clothing. Stop the engine and be sure PTO driveline is stopped before making adjustments.

If option 9201 or 9207 is ordered to make the rear PTO compatible with other manufacturer's drivelines, be sure that proper shielding is in place before operation.

TS1644 —UN—22AUG95

Rotating Drivelines

CAUTION: Metal surfaces of PTO housing may be hot to the touch during operation or at shutdown.

The optional engine rear power take-off (PTO) from John Deere transfers engine power to auxiliary equipment or moving components which may be mounted on the vehicle or trailed behind. It is an engine-driven PTO which operates whenever the engine is running.

IMPORTANT: An additional 4.0 L (4.2 qt.) of oil must be added to the crankcase for lubrication of the rear PTO option. (See ENGINE CRANKCASE OIL FILL QUANTITIES in the Specifications section.)

RG12593 —UN—06SEP02

John Deere Rear PTO (Optional)

Proper performance of the power take-off unit will be related to the care it is given. Periodically check for any oil leaks that may occur.

If the power take-off does not work properly, contact your authorized servicing dealer or engine distributor.

OUOD006,0000065 -19-12SEP06-1/1

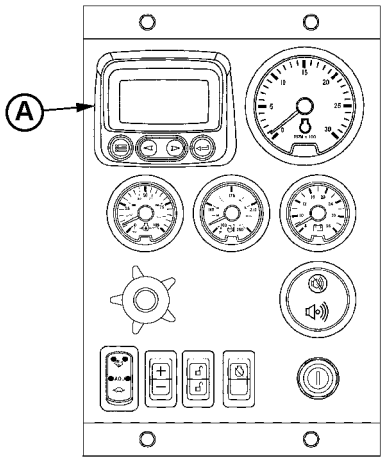
General Troubleshooting Information

Troubleshooting engine problems can be difficult. A list of possible engine problems that may be encountered is provided in this section accompanied by possible causes and corrections.

An engine wiring diagram is provided later in this section to help isolate electrical problems on power units using John Deere wiring harness and instrument (gauge) panel. The illustrated diagrams and troubleshooting information are of a general nature; final design of the overall system for your engine application may be different. See your engine distributor or servicing dealer if you are in doubt.

The engine control unit (ECU) has the ability to detect problems internally and in the electronic control system. This includes determining if any of the sensor input voltages are too high or too low, if the camshaft and crankshaft position sensor inputs are valid, and if the unit injector solenoids are responding properly.

If the ECU detects a problem with the electronic control system a diagnostic trouble code (DTC) specific to the failed system will be stored in the ECU's memory.



There are two types of DTC's:

- Active
- Inactive (stored)

Active DTCs indicate that the failure is occurring. These type of failures are sometimes called “hard” failures. They can be accessed on the diagnostic gauge (A) on the instrument panel.

Inactive DTCs indicate that a failure has occurred in the past, but is not currently occurring. This type of “stored” DTC can be caused by an “intermittent” failure. These could be problems such as a bad connection or a wire intermittently shorting to ground.

If a sensor or wiring fails and a DTC is active for the sensor, the ECU will use a substitute “limp home” value in its calculations to continue engine operation.

RG13728 —UN—11NOV04

Diagnostic Gauge On Panel

A—Diagnostic Gauge

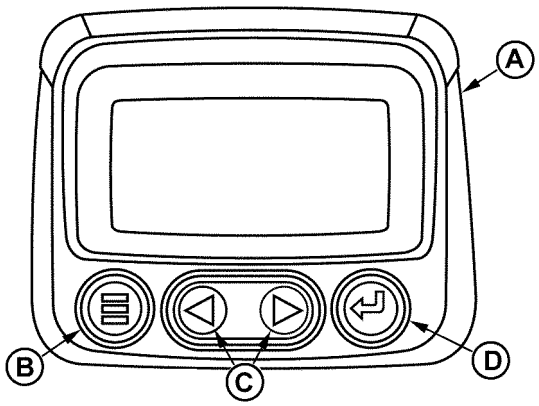
NOTE: All engines have electronic control systems which may send diagnostic trouble codes to signal problems (see DISPLAYING OF DIAGNOSTIC TROUBLE CODES, later in this section).

To access DTC's with the diagnostic gauge, see Section 15 of this manual.

1. *If fault codes are present, perform the suggested corrective actions.*
2. *If this does not correct the engine problem, contact your servicing dealer.*
3. *If engine has problems but no fault codes are displayed, refer to ENGINE TROUBLESHOOTING later in this section for problems and solutions.*

OMRGP15,0000135 -19-12SEP06-1/1

Instrument Panel Method for Retrieving Diagnostic Trouble Codes



IMPORTANT: Care should be used during diagnostic procedures to avoid damaging the terminals of connectors, sensors, and actuators. Probes should not be poked into or around the terminals or damage will result. Probes should only be touched against the terminals to make measurements.

Diagnosis of the Deere electronic control system on engines with Deere electronic instrument panel should be performed as follows:

1. Make sure all engine mechanical and other systems not related to the electronic control system are operating properly. (See ENGINE TROUBLESHOOTING later in this section.)

NOTE: Diagnostic gauge (A) uses the menu key (B) to access various engine functions, two arrow keys (C) to scroll through the engine parameter list and view the menu list, and an enter key (D) for selecting highlighted items.

2. Read and record DTC(s) displayed on LCD of diagnostic gauge (A). For procedure to access diagnostic trouble codes, refer to “Using Diagnostic Gauge to Access Engine Information”, earlier in this manual.

Displaying Of Diagnostic Trouble Codes (DTCs)

SPN/FMI CODES

Stored and active diagnostic trouble codes are output on the diagnostic gauge on the Deere electronic instrument panel according to the J1939 standard as a two-part code as shown on the tables on the following pages.

The first part is a Suspect Parameter Number (SPN) followed by a Failure Mode Identifier (FMI) code. In order to determine the exact failure, both parts (SPN and FMI) of the code are needed.

The SPN identifies the system or the component that has the failure; for example SPN 000110 indicates a failure in the engine coolant temperature circuit.

The FMI identifies the type of failure that has occurred; for example FMI 03 indicates value above normal. Combining SPN 000110 with FMI 03 yields a fault code “engine coolant temperature input voltage too high”. A corrective action will also be displayed, “check sensor and wiring”. If this check does not solve the engine fault, contact your servicing dealer.

Always contact your servicing dealer for help in correcting unsolved diagnostic trouble codes which are displayed for your engine.

Intermittent Fault Diagnostics

Intermittent faults are problems that periodically “go away”. A problem such as a terminal that intermittently doesn't make contact can cause an intermittent fault. Other intermittent faults may be set only under certain operating conditions such as heavy load, extended idle etc. When diagnosing intermittent faults, take special note of the condition of wiring and connectors since a high percentage of intermittent problems originate here. Check for loose, dirty or disconnected connectors. Inspect the wiring routing looking for possible shorts caused by contact with external parts (for example, rubbing against sharp sheet metal edges). Inspect the connector vicinity looking for wires that have pulled out of connector terminals, damaged connectors, poorly positioned terminals, and corroded or damaged terminals. Look for broken wires, damaged splices, and wire-to-wire shorts. Use good judgement if component replacement is thought to be required.

NOTE: The Engine Control Unit (ECU) is the component LEAST likely to fail.

Suggestions for diagnosing intermittent faults:

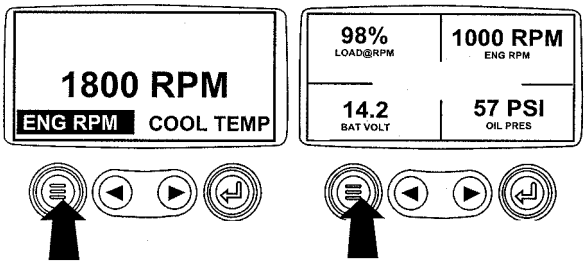
If diagnostic charts on preceding pages indicate that the problem is intermittent, try to reproduce the operating conditions that were present when the Diagnostic Trouble Code (DTC) set.

If a faulty connection or wire is suspected to be the cause of the intermittent problem: clear DTCs, then check the connection or wire by wiggling it while watching the diagnostic gauge to see if the fault resets.

Possible Causes of Intermittent Faults:

1. Faulty connection between sensor or actuator and harness.
2. Faulty contact between terminals in connector.
3. Faulty terminal/wire connection.

Electromagnetic interference (EMI) from an improperly installed 2-way radio, etc. can cause faulty signals to be sent to the ECU.



NOTE: Refer to wiring diagrams later in this section as a guide to connections and wires.

Engine Troubleshooting

NOTE: Before troubleshooting the engine, first retrieve any fault codes on the diagnostic gauge display and perform the corrective actions. (See earlier in this section.) If any problems remain, use the following charts to solve engine problems.

Symptom	Problem	Solution
Engine Will Not Crank	Weak battery	Replace battery.
	Corroded or loose battery connections	Clean battery terminals and connections.
	Defective main switch or start safety switch	Repair switch as required.
	Starter solenoid defective	Replace solenoid.
	Starter defective	Replace starter.
Hard to Start or Will Not Start	Poor fuel quality	Drain fuel and replace with quality fuel of the proper grade.
	Slow cranking speed	Check for problem in the charging/starting system.
	Too high viscosity crankcase oil	Drain crankcase oil and replace with correct viscosity oil.
	Electronic control system problem or basic engine problem	See your John Deere engine distributor or servicing dealer.
Engine Misfiring or Runs Irregularly	Electronic control system problem or basic engine problem	See your John Deere engine distributor or servicing dealer.
Lack of Engine Power	Poor fuel quality	Drain fuel and replace with quality fuel of the proper grade.
	Plugged fuel filter	Replace fuel filters.
	Engine overloaded	Reduce engine load.
	Improper crankcase oil	Drain crankcase oil and replace with correct viscosity oil.
	Electronic control system problem or basic engine problem	See your John Deere engine distributor or servicing dealer.
	Poor EGR valve (if equipped) wiring harness connection	Check EGR valve wiring harness for good connection (make sure it clicks).
Black or Gray Exhaust Smoke	Engine overloaded	Reduce engine load.
	Engine burning oil	See LUBRICATION SYSTEM TROUBLESHOOTING, later in this section.

Symptom	Problem	Solution
	Air cleaner restricted or dirty	Replace air cleaner element as required.
	Defective muffler/exhaust piping (causing back-pressure)	Replace muffler or defective piping.
	Electronic control system problem or basic engine problem	See your John Deere engine distributor or servicing dealer.
White Exhaust Smoke	Engine compression too low	Determine cause of low compression and repair as required. See your John Deere engine distributor or servicing dealer.
	Defective thermostat(s) (does not close)	Test thermostats; replace thermostats as required. (See Service as Required section.)
	Coolant entering combustion chamber (failed cylinder head gasket or cracked cylinder head)	Repair or replace as required. See your John Deere engine distributor or servicing dealer.
Engine Idles Poorly	Poor fuel quality	Drain fuel and replace with quality fuel of the proper grade.
	Air leak on suction side of air intake system	Check hose and pipe connections for tightness; repair as required.
	Electronic control system problem or basic engine problem	See your John Deere engine distributor or servicing dealer.

Engine Troubleshooting (Continued)

Symptom	Problem	Solution
Excessive Fuel Consumption	Poor fuel quality	Drain fuel and replace with quality fuel of the proper grade.
	Engine overloaded	Reduce engine load.
	Air cleaner restricted or dirty	Replace air cleaner element as required.
	Compression too low	Determine cause of low compression and repair as required.
	Leaks in fuel supply system	Locate source of leak and repair as required.
Abnormal Engine Noise	Worn main or connecting rod bearings	Determine bearing clearance. See your John Deere engine distributor or servicing dealer.
	Excessive crankshaft end play	Check crankshaft end play. See your John Deere engine distributor or servicing dealer.
	Loose main bearing caps	Check bearing clearance; replace bearings and bearing cap screws as required. See your John Deere engine distributor or servicing dealer.
	Worn connecting rod bushings and piston pins	Inspect piston pins and bushings. See your John Deere engine distributor or servicing dealer.
	Scored pistons	Inspect pistons. See your John Deere engine distributor or servicing dealer.
	Worn timing gears or excess backlash	Check timing gear backlash. See your John Deere engine distributor or servicing dealer.
	Excessive valve clearance	Check and adjust valve clearance. See your John Deere engine distributor or servicing dealer.

Electrical Troubleshooting

Symptom	Problem	Solution
Undercharged system	Excessive electrical load from added accessories.	Remove accessories or install higher output alternator.
	Excessive engine idling.	Increase engine rpm when heavy electrical load is used.
	Poor electrical connections on battery, ground strap, starter, or alternator.	Inspect and clean as necessary.
	Defective battery.	Test batteries.
	Defective alternator.	Test charging system.
Battery used too much water	Cracked battery case.	Check for moisture and replace as necessary.
	Battery charging rate too high.	Test charging system.
Batteries will not charge	Loose or corroded connections.	Clean and tighten connections.
	Sulfated or worn-out batteries.	See your authorized servicing dealer or engine distributor.
	Stretched belt or defective belt tensioner.	Adjust belt tension or replace belts.
Starter will not crank	Engine drivelines engaged.	Disengage engine drivelines.
	Loose or corroded connections.	Clean and tighten loose connections.
	Low battery output voltage or discharged battery.	Charge or replace batteries.
	Faulty start circuit relay.	See your authorized servicing dealer or engine distributor.
	Blown fuse.	Replace fuse.
		Clean battery terminals and connections.
	Defective main switch or start safety switch	Repair switch as required.
	Starter solenoid defective	Replace solenoid.
	Starter defective	Replace starter.
Starter cranks slowly	Low battery output.	Charge batteries.
	Crankcase oil too heavy.	Use proper viscosity oil.
	Loose or corroded connections.	Clean and tighten loose connections.

Precautions for Welding on Vehicles Equipped with Electronic Engine Control Unit (ECU)

IMPORTANT: ALWAYS disconnect engine control unit (ECU) connectors and engine control system-to-vehicle ground before welding. High currents or electrostatic discharge in electronic components from welding may cause permanent damage.

1. Remove the ground connection for the engine control system-to-vehicle frame.
2. Disconnect the connectors from the ECU.
3. Connect the welder ground close to the welding point and be sure ECU or other electronic components are not in the ground path.

Engine Storage Guidelines

IMPORTANT: Special considerations should be taken prior to storage when using BioDiesel. See BioDiesel Fuel in the Fuels, Lubricants, and Coolant Section.

1. John Deere engines can be stored outside for up to three months with no long-term preparation if covered by a waterproof covering. No outside storage is recommended without a waterproof covering.
2. John Deere engines can be stored in a standard overseas shipping container for up to three months with no long-term preparation.
3. John Deere engines can be stored inside for up to six months with no long-term preparation.
4. John Deere engines expected to be stored more than six months **must** have long-term storage preparation. See Preparing Engine for Long-Term Storage in the Storage Section.

OURGP12,00000DF -19-04FEB15-1/1

Preparing Engine for Long Term Storage

IMPORTANT: Any time your engine will not be used for over six months, the following recommendations for storing it and removing it from storage will help to minimize corrosion and deterioration.

IMPORTANT: Long-term storage is not advised when using BioDiesel. For storage longer than one year, use straight hydrocarbon fuel.

If BioDiesel must be used it is recommended the blend not exceed B7 and a high-quality fuel stabilizer be used. Storage should not exceed one year.

For more information see BioDiesel Fuel in the Fuels, Lubricants, and Coolants Section.

NOTE: The following storage preparations are used for long term engine storage up to one year. After that, the engine should be started, warmed up, and retreated for an extended storage period.

1. Change engine oil and replace filter. See Changing Engine Oil and Replacing Oil Filter in Lubrication and Maintenance/500 Hour Section. Used oil will not give adequate protection. Add one ounce of rust preventive oil to the engine crankcase for every quart of oil. This rust preventive oil should be an SAE 10W oil with 1-4 percent morpholine or equivalent vapor corrosion inhibitor, such as NOX RUST VCI-10 OIL from Daubert Chemical Company, Inc.
2. Service air cleaner. See Replacing Air Cleaner Filter Elements in the Service As Required Section.
3. Draining and flushing of cooling system is not necessary if engine is to be stored only for several months. However, for extended storage periods of a year or longer, it is recommended that the cooling system be drained, flushed, and refilled. Refill with appropriate coolant. See Adding Coolant in the Service As Required Section.
4. Pour three ounces of rust preventive oil into the turbocharger intake. (It may be necessary to temporarily install a short intake elbow on the turbocharger inlet to receive the oil.)
5. Prepare a tank with a solution of diesel fuel and rust preventive oil, at ten ounces of rust preventive oil per gallon of diesel fuel.
6. Remove existing lines/plugs as required, and run a temporary line from the tank to the engine fuel intake, and another temporary line from the fuel return to the tank, so rust preventive oil solution is circulated through the injection system during cranking.
7. Crank the engine several revolutions with starter (do not allow the engine to start). This will allow rust preventive oil solution to circulate.
8. Remove temporary lines installed in Step 6 above, and replace any lines/plugs previously removed.

NOTE: One gallon of fuel/oil solution can be used to treat 100 engines; two gallons to treat 200 engines, etc. The oil could then be replenished by adding an additional five ounces of rust preventive oil per gallon of solution. However, starting over with a new solution is recommended to dispose of any water or other impurities.

9. Loosen, or remove and store, fan/alternator poly-vee belt.
10. Remove and clean batteries. Store them in a cool, dry place and keep them fully charged.
11. Disengage the clutch for any driveline.
12. Clean the exterior of the engine with salt-free water and touch up any scratched or chipped painted surfaces with a good quality paint.
13. Coat all exposed (machined) metal surfaces with grease or corrosion inhibitor if not feasible to paint.
14. Seal all openings on engine with plastic bags and tape.
15. Store the engine in a dry protected place. If engine must be stored outside, cover it with a waterproof canvas or other suitable protective material and use a strong waterproof tape.

OURGP11,0000060 -19-28APR16-1/1

Removing Engine from Long-Term Storage

Refer to the appropriate section for detailed services listed below or have your authorized servicing dealer or engine distributor perform services that you may not be familiar with.

1. Remove all protective coverings from engine. Unseal all openings in engine and remove covering from electrical systems.
2. Remove the batteries from storage. Install batteries (fully charged) and connect the terminals.
3. Install fan/alternator belts if removed.
4. Fill fuel tank.
5. Perform all appropriate prestarting checks. (See DAILY PRESTARTING CHECKS in Engine Operating Guidelines Section.)

IMPORTANT: DO NOT operate starter more than 30 seconds at a time. Wait at least 2 minutes for starter to cool before trying again.

6. Crank engine for 20 seconds with starter (do not allow the engine to start). Wait 2 minutes and crank engine an additional 20 seconds to assure bearing surfaces are adequately lubricated.
7. Start engine and run at low idle and no load for several minutes. Warm up carefully and check all gauges before placing engine under load.
8. On the first day of operation after storage, check overall engine for leaks and check all gauges for correct operation.

Engine Crankcase Oil Fill Quantities

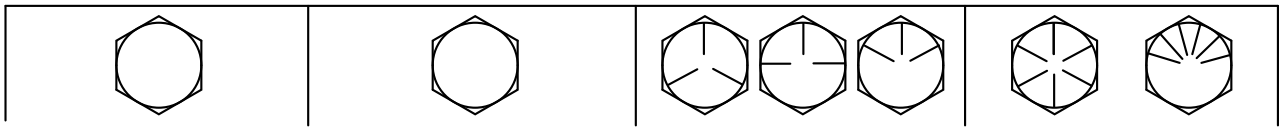
RG14341 —UN—26JUL05

Option Code Label

To determine the crankcase oil fill quantity for your engine, refer to the oil pan option code (A) located on the engine option code label affixed to the valve cover. The first two digits of the code (19) identify the oil pan group. The last two digits of each code identify the specific oil pan on your engine.

Listed below are engine crankcase oil fill quantities with filter change for each oil pan option code and PTO configuration:

Engine Model	Oil Pan Option Codes	Crankcase Oil Capacity [a]
6135HF (Without John Deere Rear PTO)	1915, 1917, 1918 1914	40.0 L (42.3 qt.) 60.0 L (63.4 qt.)



[a] *Crankcase oil capacity may vary slightly from amount shown. ALWAYS fill crankcase to within crosshatch area on dipstick. DO NOT overfill.*

NOTE: If engine is equipped with John Deere PTO, add an additional 4 L (4.2 qt) of oil to lubricate PTO gear train.

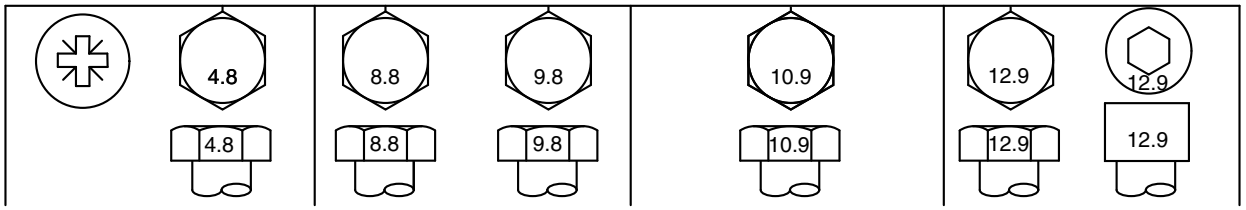
Torque values listed are for general use only, based on the strength of the bolt or screw. DO NOT use these values if a different torque value or tightening procedure is given for a specific application. For plastic insert or crimped steel type lock nuts, for stainless steel fasteners, or for nuts on U-bolts, see the tightening instructions for the specific application. Shear bolts are designed to fail under predetermined loads. Always replace shear bolts with identical grade.

Replace fasteners with the same or higher grade. If higher grade fasteners are used, tighten these to the strength of the original. Make sure fastener threads are clean and that you properly start thread engagement. When possible, lubricate plain or zinc plated fasteners other than lock nuts, wheel bolts or wheel nuts, unless different instructions are given for the specific application.

[a]Grade 2 applies for hex cap screws (not hex bolts) up to 6 in. (152 mm) long. Grade 1 applies for hex cap screws over 6 in. (152 mm) long, and for all other types of bolts and screws of any length.



[b]"Lubricated" means coated with a lubricant such as engine oil, fasteners with phosphate and oil coatings, or 7/8 in. and larger fasteners with JDM F13C, F13F or F13J zinc flake coating.

[c]"Dry" means plain or zinc plated without any lubrication, or 1/4 to 3/4 in. fasteners with JDM F13B, F13E or F13H zinc flake coating.

Torque values listed are for general use only, based on the strength of the bolt or screw. DO NOT use these values if a different torque value or tightening procedure is given for a specific application. For stainless steel fasteners or for nuts on U-bolts, see the tightening instructions for the specific application. Tighten plastic insert or crimped steel type lock nuts by turning the nut to the dry torque shown in the chart, unless different instructions are given for the specific application.

Shear bolts are designed to fail under predetermined loads. Always replace shear bolts with identical property class. Replace fasteners with the same or higher property class. If higher property class fasteners are used, tighten these to the strength of the original. Make sure fastener threads are clean and that you properly start thread engagement. When possible, lubricate plain or zinc plated fasteners other than lock nuts, wheel bolts or wheel nuts, unless different instructions are given for the specific application.

[a] *"Lubricated" means coated with a lubricant such as engine oil, fasteners with phosphate and oil coatings, or M20 and larger fasteners with JDM F13C, F13F or F13J zinc flake coating.*

[b] *"Dry" means plain or zinc plated without any lubrication, or M6 to M18 fasteners with JDM F13B, F13E or F13H zinc flake coating.*

Lubrication and Maintenance Records

Using Lubrication and Maintenance Records

Refer to specific Lubrication and Maintenance section for detailed service procedures.

1. Keep a record of the number of hours you operate your engine by regular observation of hour meter.
2. Check your record regularly to learn when your engine needs service.
3. DO ALL the services within an interval section. Write the number of hours (from your service records) and the date in the spaces provided. For a complete listing of all items to be performed and the service intervals required, refer to the quick-reference chart near the front of the Lubrication and Maintenance section.

IMPORTANT: The service recommendations covered in this manual are for the accessories that are provided by John Deere. Follow manufacturer's service recommendations for servicing engine-driven equipment not supplied by Deere.

John Deere Warranty in OEM Applications

Overview

This section focuses on John Deere engines marketed in products manufactured by companies other than John Deere or its affiliates, and on John Deere repower engines in all applications. Herein appears the original warranty applicable to the engine as delivered to the retail purchaser on or after 1 May 2010. The following is information about the warranty and warranty service.

NOTE: "John Deere" means John Deere Power Systems with respect to users in the United States, John Deere Limited with respect to users in Canada, and Deere & Company or its subsidiary responsible for making John Deere equipment in other countries where the user is located.

Promptly register your engine online at https://www.johndeere.com/enginewarranty

When Warranty Service Is Needed

The nearest dealer stands ready with genuine parts and trained and equipped personnel should the need arise. If following the Operator's Manual delivered with the engine/machine are not adequate to correct an engine problem, contact the nearest John Deere service dealer for assistance. Authorized engine service dealers can be found at: https://www.johndeere.com/ (click on "Dealer Locator").

NOTE: When requesting warranty service, the purchaser must be prepared to provide proof that the engine is within the warranty period.

The following information is always required: Engine serial number, date of delivery, engine owner, name and location of dealer and specific person contacted, date of contact, nature of engine problem, and outcome of the service dealer contact.

Given that normally it is the dealer contacted who in the end will provide the service required, maintaining a purchaser-dealer relationship of mutual respect from the beginning is always helpful.

Privacy Notice

At John Deere your privacy is important to us. We collect, use, and disclose your personal information in accordance with the John Deere privacy statement. For instance, we collect, use, and disclose your personal information to provide you with the products and services that you request; to communicate with you as our customer (examples include warranty and product improvement programs) and to meet safety and legal requirements; and for marketing and promotional purposes. Sometimes, we may ask our John Deere affiliates, dealers, or business partners to do work for us which involves your information. For complete details on your privacy rights and to obtain a copy of the John Deere Privacy Statement, please visit our website at https://www.johndeere.com/.

Warranty Duration

Unless otherwise provided in writing by John Deere, John Deere makes the following warranty to the first retail purchaser and each subsequent purchaser (if purchase is made prior to the expiration of applicable warranty) of each John Deere new off-highway engine marketed as part of a product manufactured by a company other than John Deere or its affiliates and on each John Deere engine used in an off-highway repower application:

- 12 months, unlimited hours of use, or
- 24 months and before the accumulation of 2000 hours of use.

NOTE: In the absence of a functional hourmeter, hours of use will be determined on the basis of 12 hours of use per calendar day.

Warranty Coverage

This warranty applies to the engine and to integral components and accessories sold by John Deere, and delivered to the first retail purchaser on or after 1 May 2010.

All John Deere-warranted parts and components of John Deere engines which, as delivered to the purchaser, are defective in materials and/or workmanship will be repaired or replaced, as John Deere elects. Warrantable repairs will be made without charge for parts or engine repair labor, including reasonable labor costs to remove and reinstall non-engine parts or components of the equipment in which the engine is installed. If required, reasonable labor costs for engine removal and reinstallation will also be included. All coverage is based on the defect appearing within the warranty period as measured from the date of delivery to the first retail purchaser.

Obtaining Warranty Service

Warranty service must be requested of the nearest authorized John Deere engine service outlet before the expiration of the warranty. An *authorized* service outlet is a John Deere engine distributor, a John Deere engine service dealer, or a John Deere equipment dealer selling and servicing equipment with an engine of the type covered by this warranty. (See When Warranty Service is Needed above.)

Authorized service outlets will use only new or remanufactured parts or components furnished or approved by John Deere.

NOTE: Authorized engine service locations are listed on the Internet at https://www.johndeere.com/ (Click on "Dealer Locator".)

At the time of requesting warranty service, the purchaser must be prepared to present evidence of the date of delivery of the engine.

Continued on next page

John Deere reimburses authorized service outlets for limited travel expenses incurred in making warranty service repairs in non-John Deere applications when travel is actually performed. The limit, as of the date of publication of this booklet, is US$400.00 (US$500.00 if engine is marine) or equivalent. **If distances and travel times are greater than reimbursed by John Deere, the service outlet will charge the purchaser for the difference.**

Warranty Exclusions

John Deere's obligations will not apply to components and accessories which are not furnished or installed by John Deere, nor to failures caused by such items, except as required by law.

Purchaser's Responsibilities

The cost of normal maintenance and depreciation.

Periodic cleaning of the diesel particulate filter (DPF).

Consequences of negligence, misuse, or accident involving the product, or improper application, installation, or storage.

Consequences of service performed by someone other than an authorized John Deere engine service outlet.

Consequences of any product modification or alteration not approved by John Deere, including, but not limited to, tampering with engine fuel and air delivery systems.

Consequences of failure of non-product components.

Consequences of fuels, lubricants, or coolants that fail to meet the specifications and requirements listed in the Operator's Manual.

The effects of cooling system neglect as manifested in cylinder liner or cylinder block cavitation ("pitting, "erosion", "electrolysis").

Any premium for overtime labor requested by the purchaser.

Costs of transporting the product or the equipment in which it is installed to and from the location at which the warranty service is performed, if such costs are in excess of the travel reimbursement payable to the dealer had the warranty service been performed at the product's location.

Costs incurred in gaining access; for example, overcoming physical barriers such as walls, fences, floors, decks, or similar structures impeding access to the product, rental of cranes or similar, or construction of ramps or lifts or protective structures for product removal and reinstallation.

Incidental travel costs including meals, lodging, and similar, and any travel time or mileage costs in excess of the maximum allowance.

Service outlet costs incurred in solving or attempting to solve non-warrantable problems.

Services performed by a party other than an authorized John Deere service dealer.

Charges by dealers for initial start-up and inspection deemed unnecessary by John Deere when an Operator's Manual is supplied with the product are followed.

Costs related to interpretation or translation services.

No Representations or Implied Warranty

Where permitted by law, neither John Deere nor any company affiliated with it makes any guaranties, warranties, conditions, representations or promises, express or implied, oral or written, as to the nonoccurrence of any defect or the quality of performance of its engines other than those set forth in this booklet, and DOES NOT MAKE ANY IMPLIED WARRANTY OR CONDITIONS OF MERCHANTABILITY OR FITNESS otherwise provided for in the Uniform Commercial Code or required by any Sale of Goods Act or any other statute. This exclusion includes fundamental terms. In no event will a John Deere engine distributor or engine service dealer, John Deere equipment dealer, or John Deere or any company affiliated with John Deere be liable for incidental or consequential damages or injuries including, but not limited to, loss of profits, loss of crops, rental of substitute equipment or other commercial loss, damage to the equipment in which the engine is installed or for damage suffered by purchaser as a result of fundamental breaches of contract or breach of fundamental terms, unless such damages or injuries are caused by the gross negligence or intentional acts of the foregoing parties.

Remedy Limitation

The remedies set forth in this warranty are the purchaser's exclusive remedies in connection with the performance of, or any breach of guaranty, condition, or warranty in respect of new John Deere engines. In the event the above warranty fails to correct purchaser's performance problems caused by defects in workmanship and/or materials, purchaser's exclusive remedy shall be limited to payment by John Deere of actual damages in an amount not to exceed the cost of the engine.

No Seller's Warranty

No person or entity, other than John Deere, who sells the engine or product in which the engine has been installed makes any guaranty or warranty of its own on any engine warranted by John Deere unless it delivers to the purchaser a separate written guaranty certificate specifically guaranteeing the engine, in which case John Deere shall have no obligation to the purchaser. Neither original equipment manufacturers, engine or equipment distributors, engine or equipment dealers, nor any other person or entity, has any authority to make any representation or promise on behalf of John Deere or to modify the terms or limitations of this warranty in any way.

Replacement Parts Warranty

John Deere and John Deere Reman parts and components (excluding replacement engines) installed during engine warranty service are warranted for the remaining warranty period of the engine or the applicable warranty term for the installed service part, whichever is greater. A new or remanufactured engine replacing a failed engine under warranty is warranted for 90 days or the remaining warranty period of the original engine, whichever is greater.

Warranty Transfer

The remainder of the original engine warranty and the emissions control-related warranty may be transferred to a subsequent owner of the engine. The Engine Warranty Transfer card should be used to report the transfer to John Deere. If a card is not available, contact your Dealer or simply send the following Information to JDPS Warranty Administration at Diesel-US@JohnDeere.com.

1. The complete 13-character engine serial number.
2. The name and mailing address of the original purchaser.
3. Delivery date to the original purchaser.
4. Hours at the time of transfer.
5. Date of transfer to the new owner.
6. Name and mailing address of the new owner.
7. How the engine/drivetrain being used, i.e., what equipment it powers, by manufacturer and model.
8. Equipment it powers, by manufacturer and model.

Purchased Extended Warranty

Extended warranty may be purchased on most engines in many areas of the world. John Deere engine distributors and equipment dealers, and dealers of manufacturers using John Deere engines in their products, have details. John Deere may also be contacted at U.S.A. fax number 1-309-749-0816, or in Europe fax number 33.2.38.84.62.66.

Emissions Warranties

Emissions warranties appear in the Operator's Manual furnished with the engine/machine. **(Warning: Statutes providing severe penalties for tampering with emissions controls may apply at the user's location.)** John Deere may also be contacted at U.S.A. fax number 1-309-749-0816; or in Europe fax number 33.2.38.84.62.66.

Local Warranty Requirements

Warranties required by local statutes will be furnished by the seller.

Option Codes (Engine Manufacturing Configuration)

When in need of engine replacement parts, your authorized John Deere service dealer will need to know the corresponding "Option Codes" for your engine. The option code label on the engine rocker arm cover may become damaged over time. By recording the four-digit codes when the engine is new, and storing this manual where it can be found when parts are needed, fast, accurate parts ordering and service will be assured. (See Engine Option Codes in the Record Keeping Section).

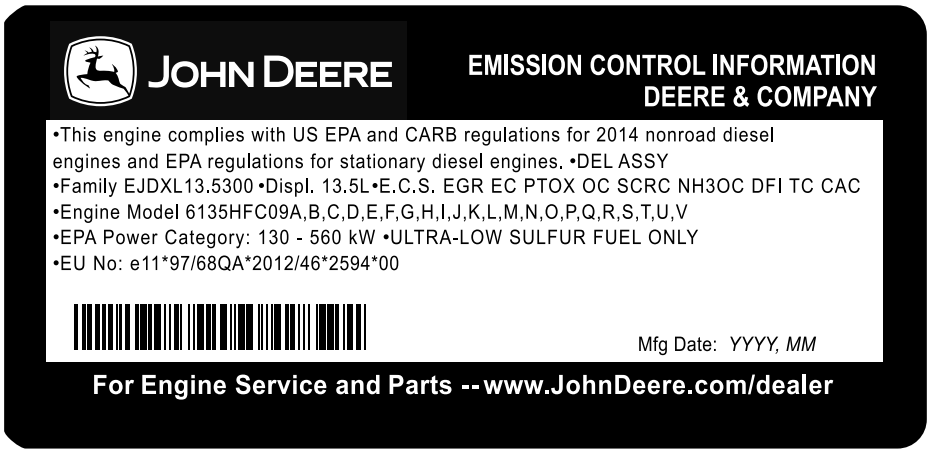
Should there be a question about an engine option code, note the engine serial number and call 1-800-JDENGINE from the U.S.A. or Canada, or fax U.S.A. number 1-309-749-0816; or E-mail at diesel-us@johndeere.com, Attention: Warranty Administration; or in Europe fax number 33.2.38.84.62.66, or E-mail at saranservice@johndeere.com.

Registering The Engine For Warranty

Completion and submission of the John Deere Engine Warranty Registration form (cut out sheet found in this manual) is very important. John Deere will not deny warranty service on an engine within its warranty period if the engine has not been registered. However, registering your engine will assure your servicing dealer that the engine is within the warranty period.

The easiest way to register your engine is via the Internet. Go to website https://www.johndeere.com/enginewarranty You can use the sheet in this manual to gather the information needed to register the warranty.

NOTE: Information provided on the form must be legible!



Typing is preferred, but legible handwritten reports are acceptable. "Block" numbers and Roman alphabet letters should be used. For example: 1,2,3,4 and A, B, C, D.

All requested information should be given. Much of it contributes to reports, including those required by governments.

The purchaser's telephone number or E-mail address allows John Deere to make contact should there be questions concerning the registration. The purchaser should sign and date the form.

Emissions Control System Certification Label

RG24291 —UN—18SEP13

Engine Emissions Label

CAUTION: Statutes providing severe penalties for tampering with emissions controls may apply to the user or dealer.

The emissions warranty applies to those engines marketed by John Deere that have been certified by the United States Environmental Protection Agency (EPA) and/or California Air Resources Board (CARB); and used in the United States and Canada in Non-road equipment. The presence of an emissions label like the one shown signifies that the engine has been certified with the EPA and/or CARB. The EPA and CARB warranties only apply to new engines having the certification label affixed to the engine and sold as stated above in the geographic areas. The presence of an EU number signifies that the engine has been certified with the European Union countries per Directive 97/68/EC. The EPA and/or CARB emissions warranties do not apply to the EU countries.

The emissions label has applicable US EPA and/or CARB regulatory year. The regulatory year determines which warranty statement is applicable to engine. See “EPA Non-road Emissions Control Warranty Statement—Compression Ignition” and “CARB Non-road Emissions Control Warranty Statement—Compression Ignition”. For additional regulatory year warranty statements, see www.JohnDeere.com or contact the nearest John Deere service dealer for assistance.

Emission Control System(s) Laws

The U.S. EPA and California ARB prohibit the removal or rendering inoperative of any device or element of design installed on or in engines/equipment in compliance with applicable emission regulations prior to or after the sale and delivery of the engines/equipment to the ultimate purchaser.

U.S. AND CANADA EMISSION CONTROL WARRANTY STATEMENT
YOUR WARRANTY RIGHTS AND OBLIGATIONS

To determine if the John Deere engine qualifies for the additional warranties set forth below, look for the "Emissions Control Information" label located on the engine. If the engine is operated in the United States or Canada and the Emissions Control information label states: "This engine complies with US EPA regulations for nonroad and stationary diesel engines", or "This engine conforms to US EPA nonroad compression-ignition regulations", refer to the "U.S. and Canada Emission Control Warranty Statement." If the engine is operated in California, and the label states: "This engine complies with US EPA and CARB regulations for nonroad diesel engines", or "This engine conforms to US EPA and California nonroad compression-ignition emission regulations", also refer to the "California Emission Control Warranty Statement."

Warranties stated on this certificate refer only to emissions-related parts and components of your engine. The complete engine warranty, less emissions-related parts and components, is provided separately. If you have any questions about your warranty rights and responsibilities, you should contact John Deere at 1-319-292-5400.

JOHN DEERE'S WARRANTY RESPONSIBILITY

John Deere warrants to the ultimate purchaser and each subsequent purchaser that this off-road diesel engine including all parts of its emission-control system was designed, built and equipped so as to conform at the time of the sale with Section 213 of the Clean Air Act and is free from defects in materials and workmanship which would cause the engine to fail to conform with applicable US EPA regulations for a period of five years from the date the engine is placed into service or 3,000 hours of operation, whichever first occurs.

Where a warrantable condition exists, John Deere will repair or replace, as it elects, any part or component with a defect in materials or workmanship that would increase the engine's emissions of any regulated pollutant within the stated warranty period at no cost to you, including expenses related to diagnosing and repairing or replacing emission-related parts. Warranty coverage is subject to the limitations and exclusions set forth herein. Emission- related components include engine parts developed to control emissions related to the following:

Air-Induction System
Fuel System
Ignition System
Exhaust Gas Recirculation Systems
Aftertreatment Devices
Crankcase Ventilation Valves
Sensors
Engine Electronic Control Units

EMISSION WARRANTY EXCLUSIONS

John Deere may deny warranty claims for malfunctions or failures caused by:

- Non-performance of maintenance requirements listed in the Operator's Manual
- The use of the engine/equipment in a manner for which it was not designed
- Abuse, neglect, improper maintenance or unapproved modifications or alterations
- Accidents for which it does not have responsibility or by acts of God

The off-road diesel engine is designed to operate on diesel fuel as specified in the Fuels, Lubricants and Coolants section in the Operators Manual. Use of any other fuel can harm the emissions control system of the engine/equipment and is not approved for use.

To the extent permitted by law John Deere is not liable for damage to other engine components caused by a failure of an emission-related part, unless otherwise covered by standard warranty.

THIS WARRANTY IS EXPRESSLY IN LIEU OF ANY OTHER WARRANTIES, EXPRESS OR IMPLIED, INCLUDING ANY WARRANTY OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. REMEDIES UNDER THIS WARRANTY ARE LIMITED TO THE PROVISIONS OF MATERIAL AND SERVICES AS SPECIFIED HEREIN. WHERE PERMITTED BY LAW, NEITHER JOHN DEERE NOR ANY AUTHORIZED JOHN DEERE ENGINE DISTRIBUTOR, DEALER, OR REPAIR FACILITY OR ANY COMPANY AFFILIATED WITH JOHN DEERE WILL BE LIABLE FOR INCIDENTAL OR CONSEQUENTIAL DAMAGES.

CALIFORNIA EMISSIONS CONTROL WARRANTY STATEMENT:

The California Air Resources Board (CARB) is pleased to explain the emission-control system warranty on 2013 through 2015 off-road diesel engines. In California, new off-road engines must be designed, built and equipped to meet the State’s stringent anti-smog standards. John Deere must warrant the emission control system on your engine for the periods of time listed below provided there has been no abuse, neglect or improper maintenance of your engine.

Your emission control system may include parts such as the fuel injection system and the air induction system. Also included may be hoses, belts, connectors and other emission-related assemblies.

John Deere warrants to the ultimate purchaser and each subsequent purchaser that this off-road diesel engine was designed, built, and equipped so as to conform at the time of sale with all applicable regulations adopted by CARB and is free from defects in materials and workmanship which would cause the failure of a warranted part to be identical in all material respects to the part as described in John Deere's application for certification for a period of five years from the date the engine is delivered to an ultimate purchaser or 3,000 hours of operation, whichever occurs first for all engines rated at 19 kW and greater. In the absence of a device to measure hours of use, the engine shall be warranted for a period of five years.

EMISSIONS WARRANTY EXCLUSIONS:

John Deere may deny warranty claims for failures caused by the use of an add-on or modified part which has not been exempted by the CARB. A modified part is an aftermarket part intended to replace an original emission-related part which is not functionally identical in all respects and which in any way affects emissions. An add-on part is any aftermarket part which is not a modified part or a replacement part.

In no event will John Deere, any authorized engine distributor, dealer, or repair facility, or any company affiliated with John Deere be liable for incidental or consequential damage.

JOHN DEERE'S WARRANTY RESPONSIBILITY:

Where a warrantable condition exists, John Deere will repair or replace, as it elects, your off-road diesel engine at no cost to you, including diagnosis, parts or labor. Warranty coverage is subject to the limitations and exclusions set forth herein. The off-road diesel engine is warranted for a period of five years from the date the engine is delivered to an ultimate purchaser or 3,000 hours of operation, whichever occurs first. The following are emissions-related parts:

Air Induction System

- Intake manifold
- Turbocharger
- Charge air cooler

Fuel Metering system

- Fuel injection system

Exhaust Gas Recirculation

- EGR valve

Catalyst or Thermal Reactor Systems

- Catalytic converter
- Exhaust manifold

Emission control labels

Particulate Controls

- Any device used to capture particulate emissions
- Any device used in the regeneration of the capturing system
- Enclosures and manifolding
- Smoke Puff Limiters

Positive Crankcase Ventilation (PCV) System

- PCV valve
- Oil filler cap

Advanced Oxides of Nitrogen (NOx) Controls

- NOx absorbers and catalysts

SCR systems and urea containers/dispensing systems

Miscellaneous Items used in Above Systems

- Electronic control units, sensors, actuators, wiring harnesses, hoses, connectors, clamps, fittings, gasket, mounting hardware

Any warranted emissions-related part scheduled for replacement as required maintenance is warranted by John Deere for the period of time prior to the first scheduled replacement point for the part. Any warranted emissions-related part not scheduled for replacement as required maintenance or scheduled only for regular inspection is warranted by John Deere for the stated warranty period.

OWNER'S WARRANTY RESPONSIBILITIES:

As the off-road diesel engine owner you are responsible for the performance of the required maintenance listed in your Operator's Manual. John Deere recommends that the owner retain all receipts covering maintenance on the off-road diesel engine, but John Deere cannot deny warranty solely for the lack of receipts or for the owner's failure to ensure the performance of all scheduled maintenance. However, as the off-road diesel engine owner, you should be aware that John Deere may deny you warranty coverage if your off-road diesel engine or a part has failed due to abuse, neglect, improper maintenance or unapproved modifications.

The off-road diesel engine is designed to operate on diesel fuel as specified in the Fuels, Lubricants and Coolants section in the Operators Manual. Use of any other fuel may result in the engine no longer operating in compliance with applicable emissions requirements.

The owner is responsible for initiating the warranty process, and should present the machine to the nearest authorized John Deere dealer as soon as a problem is suspected. The warranty repairs should be completed by the authorized John Deere dealer as quickly as possible.

Emissions regulations require the customer to bring the unit to an authorized servicing dealer when warranty service is required. As a result, John Deere is NOT liable for travel or mileage on emissions warranty service calls.

Emissions Control Warranty Statement 2013 through 2015

DXLOGOV1 —UN—28APR09

JOHN DEERE

CALIFORNIA EMISSIONS CONTROL WARRANTY STATEMENT
YOUR WARRANTY RIGHTS AND OBLIGATIONS

To determine if the John Deere engine qualifies for the additional warranties set forth below, look for the “Emission Control Information” label located on the engine. If the engine is operated in the United States or Canada and the engine label states: “This engine complies with US EPA regulations for nonroad and stationary diesel engines”, or “This engine complies with US EPA regulations for stationary emergency diesel engines”, refer to the “U.S. and Canada Emission Control Warranty Statement.” If the engine is operated in California, and the engine label states: “This engine complies with US EPA and CARB regulations for nonroad diesel engines” also refer to the “California Emissions Control Warranty Statement.”

Warranties stated on this certificate refer only to emissions-related parts and components of your engine. The complete engine warranty, less emission-related parts and components, is provided separately. If you have any questions about your warranty rights and responsibilities, you should contact John Deere at 1-319-292-5400.

CALIFORNIA EMISSIONS CONTROL WARRANTY STATEMENT:

The California Air Resources Board (CARB) is pleased to explain the emission-control system warranty on 2013 through 2015 off-road diesel engines. In California, new off-road engines must be designed, built and equipped to meet the State’s stringent anti-smog standards. John Deere must warrant the emission control system on your engine for the periods of time listed below provided there has been no abuse, neglect or improper maintenance of your engine.

Your emission control system may include parts such as the fuel injection system and the air induction system. Also included may be hoses, belts, connectors and other emission-related assemblies.

Introduction

This manual lists service replacement parts for John Deere engine models 6135HF.

At the time of print this manual applied to the engine models listed in the Model Index. On occasion this manual may apply to engines not listed in the Model Index.

Information in this publication represents data available at the time of print. The generator set manufacturer reserves the right to change this publication and the products represented without notice and without any obligation or liability whatsoever.

This manual includes the following main sections:

Table of Contents. Lists the sections of the manual.

Introduction (and other information sections). Contains introductory material about part numbers, illustrations, and hardware.

Index. Lists the engine models and groups.

Group Parts Lists. List the part numbers of parts in the groups.

Numbering System Significance

This manual uses the following numbering systems:

Engine Model. The product identification number located on the engine nameplate. Engines break down into groups.

Group Number. A unique number representing a parts group needed to assemble an engine function. For example, Group 1 is the Air Intake group.

Variation Number. A group might have several variations. Each variation performs the same function with different parts lists. For example, a 12-volt alternator and 24-volt alternator both perform the same function, but, with different parts. Each difference requires a group variation or module number.

Part Number. The part number identifies an individual assembly, subassembly, component, or accessory kit.

Illustrations

Illustrations (or exploded-view drawings) best representing the widest range of variations accompany most groups in this manual. Illustrations do not depict all details and may not show all parts. Do not use illustrations for assembly or disassembly.

How to Find Part Numbers

Use the following steps to locate a service replacement part.

1. Locate the engine nameplate to **identify the engine model number**.
2. **Turn to the Model Index**. The first column lists the engine model numbers. The headings identify the groups of parts that make up the engine.
3. **Identify the group** most likely to include the service part number.
4. **Find the group variation number** at the intersection of the model row and the group column. Note the variation number.
5. **Page forward to locate the group** identified in step 3 or find the appropriate page in the Table of Contents.
6. **Find the part on the illustration** and note the item number of the part or **find the part description in the parts list**.
7. Select **the part number that corresponds to your group variation**. The first column lists the illustration item number. Find the variation identified in the Model Index in the appropriate column on the right side of the parts list table. Find the quantity used at the intersection of the item number row and the variation column. A blank space at the intersection means the variation/module does not use that part number.

Hardware References

Many common hardware items do not appear in parts manuals or will appear as common hardware entries. A common hardware entry lists the size of the hardware. For example, an item that appears as “Hardware, 3/8-16” in the text means that the piece is 3/8-16 size. Obtain common hardware locally.

Some hardware items require a specific size or some other characteristic. In that case, use the part number listed in the text.

When replacing hardware, do not substitute inferior grade hardware. Replacement hardware grade should be equal to or better than the grade of the manufacturer’s original hardware.

Introduction

This manual lists service replacement parts for generator set models as listed on the front cover.

Information in this publication represents data available at the time of print. Kohler Co. reserves the right to change this publication and the products represented without notice and without any obligation or liability whatsoever.

This manual includes the following main sections:

Table of Contents. Lists the sections of the manual.

Introduction (and other information sections). Contains introductory material about part numbers, illustrations, and hardware.

Specification Number Index. Lists the generator set specs and groups.

Group Parts Lists. List the part numbers of parts in the groups.

Kit Sections. List modules and accessories and their parts.

Appendices. Include Abbreviations, Common Hardware Application Guidelines, General Torque Specifications, Common Hardware Identification, and Common Hardware List.

Numbering System Significance

This manual uses the following numbering systems:

Specification Number. The product identification number located on the generator set nameplate. Specification numbers break down into groups.

Group Number. A unique number representing a parts group needed to assemble a generator set function. For example, Group 101 is the Air Intake group.

Variation or Module Number. A group might have several variations. Each variation performs the same function with different parts lists. For example, a 50 Hz generator alternator and a 60 Hz generator alternator both perform the same function; however, with different parts. Each difference requires a group variation or module number.

Part Number. The part number identifies an individual assembly, subassembly, component, or accessory kit.

Illustrations

Illustrations (or exploded-view drawings) best representing the widest range of variations accompany most groups in this manual. Illustrations do not depict all details and may not show all parts. Do not use illustrations for assembly or disassembly.

How to Find Part Numbers

Use the following steps to locate a service replacement part.

1. Locate the generator set nameplate to **identify the generator set spec number**.
2. Locate a second generator set nameplate listing accessories to **identify installed modules**. On some models the accessory nameplate is mounted inside the generator junction box.
3. **Turn to the Specification Number Index**. The first column lists the generator set spec numbers. The headings identify the groups of parts that make up the generator set.
4. **Identify the group** most likely to include the service part number.
5. **Find the group variation number** at the intersection of the spec number row and the group column. Note the variation number.
6. **Page forward to locate the group** identified in step 4 or find the appropriate page in the Table of Contents.
7. **Find the part on the illustration** and note the item number of the part or **find the part description in the parts list**.
8. Select **the part number that corresponds to your group variation**. The first column lists the illustration item number. Find the variation identified in the Specification Number Index or the module number found on the generator set nameplate in the appropriate column on the right side of the parts list table. Find the quantity used at the intersection of the item number row and the variation column. A blank space at the intersection means the variation/module does not use that part number.

Hardware References

Many common hardware items do not appear in parts manuals or will appear as common hardware entries. A common hardware entry lists the size of the hardware. For example, an item that appears as *Hardware, 3/8-16* in the text means that the piece is 3/8-16 size. Obtain common hardware locally or, if contacting the factory, use the Common Hardware List in the appendix to identify the common hardware part number and specifications. See Common Hardware Application Guidelines in the appendix for mating hardware instructions.

Some hardware items require a specific size or some other characteristic. In that case, use the part number listed in the text.

When replacing hardware, do not substitute inferior grade hardware. Replacement hardware grade should be equal to or better than the grade of the manufacturer's original hardware. Use the Common Hardware List in the appendix to identify the common hardware hardness.

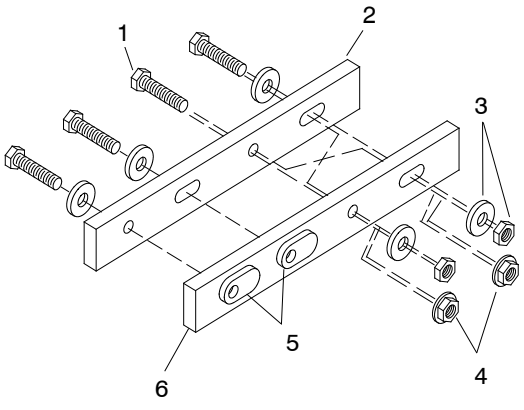
Appendix B Common Hardware Application Guidelines

Use the information below and on the following pages to identify proper fastening techniques when no specific reference for reassembly is made.

Bolt/Screw Length: When bolt/screw length is not given, use Figure 1 as a guide. As a general rule, a minimum length of one thread beyond the nut and a maximum length of 1/2 the bolt/screw diameter beyond the nut is the preferred method.

Washers and Nuts: Use split lock washers as a bolt locking device where specified. Use SAE flat washers with whiz nuts, spiralock nuts, or standard nuts and preloading (torque) of the bolt in all other applications.

See Appendix C, General Torque Specifications, and other torque specifications in the service literature.



1. 1/2 of bolt diameter
2. Min. 1 full thread beyond top of nut
3. Below top of nut

Figure 1 Acceptable Bolt Lengths

Steps for common hardware application:

1. Determine entry hole type: round or slotted.
2. Determine exit hole type: fixed female thread (weld nut), round, or slotted.

   For round and slotted exit holes, determine if hardware is greater than 1/2 inch in diameter, or 1/2 inch in diameter or less. Hardware that is *greater than 1/2 inch* in diameter takes a standard nut and SAE washer. Hardware *1/2 inch or less* in diameter can take a properly torqued whiz nut or spiralock nut. See Figure 2.
3. Follow these SAE washer rules after determining exit hole type:
   a. Always use a washer between hardware and a slot.
   b. Always use a washer under a nut (see 2 above for exception).
   c. Use a washer under a bolt when the female thread is fixed (weld nut).
4. Refer to Figure 2, which depicts the preceding hardware configuration possibilities.

1. Cap screw
2. Entry hole types
3. Standard nut and SAE washer
4. Whiz nut or spiralock: up to 1/2 in. dia. hardware
5. Weld nuts: above 1/2 in. dia. hardware
6. Exit hole types

Notes:

1. The torque values above are general guidelines. Always use the torque values specified in the service manuals and/or assembly drawings when they differ from the above torque values.
2. The torque values above are based on new plated threads. Increase torque values by 15% if non-plated threads are used.
3. Hardware threaded into aluminum must have either two diameters of thread engagement or a 30% or more reduction in the torque to prevent stripped threads.
4. Torque values are calculated as equivalent stress loading on American hardware with an approximate preload of 90% of the yield strength and a friction coefficient of 0.125.
